#### **Discrete Logarithm Problem**

http://koclab.org

#### Exponentiation and Logarithms in a General Group

• In a multiplicative group  $(S, \otimes)$  with a primitive element  $g \in S$ , the exponentiation operation for a positive x is the computation of y in

$$y = g^{x} = \overbrace{g \otimes g \otimes \cdots \otimes g}^{x \text{ terms}}$$

• On the other hand, in an additive group  $(S, \oplus)$  with a primitive element  $g \in S$ , the point multiplication operation is the computation of y in

$$y = [x]g = \overbrace{g \oplus g \oplus \cdots \oplus g}^{x \text{ terms}}$$

In both cases, the discrete logarithm problem (DLP) is defined as:

Given y and g, Compute x

4 D > 4 db > 4 d > 5 > d = 2 > 9Q(4)

# Discrete Logarithms in Public-Key Cryptography

- If the DLP is difficult in a given group, we can use it to implement several public-key cryptographic algorithms, for example,
   Diffie-Hellman key exchange method, ElGamal public-key encryption method, and the Digital Signature Algorithm
- Two types of groups are noteworthy:
  - ullet The multiplicative group  $\mathcal{Z}_p^*$  of integers modulo a prime p
  - The additive group of elliptic curves defined over finite fields
- The DLP problem in these groups are known to be difficult

<ロ > ← □ > ← □ > ← □ > ← □ = ・ の へ (で

ttp://koclab.org Cetin Kaya Koç Winter 2017 3 /

# Discrete Logarithm in $(Z_n, + \text{mod } n)$

- There may also be other groups worth considering
- However, the DLP is trivial in many groups
- For example, the DLP in additive mod p group is trivial
- "Exponentiation" in this group is defined as

$$y = [x]g = g + g + \cdots + g$$

where g is a primitive element in the group, x is an integer, y is an element of the group (an integer in  $Z_n$ ), and the + operation is the addition mod n

◆ロト ◆回 ト ◆ 直 ト ◆ 直 ・ り へ ○

ttp://koclab.org Çetin Kaya Koç Winter 2017 4

5 / 58

# Discrete Logarithm in $(Z_n, + \text{mod } n)$

x is easily solvable from the above since

$$x = g^{-1} \cdot y \pmod{n}$$

where  $y^{-1}$  is the multiplicative inverse of  $y \mod n$ 

- Consider  $(Z_{11}, + \text{ mod } 11)$  where any nonzero element is primitive
- Any DLP in  $(Z_{11}, + \text{ mod } 11)$  is easily solvable, for example,

$$2 = [x]3 \pmod{11}$$

is solved as

$$x = 3^{-1} \cdot 2 \pmod{11}$$
  
=  $4 \cdot 2 \pmod{11}$   
= 8

4 L P 4 M P 4 Z P 4 Z P 2 2 9) U(\*

# Discrete Logarithms in $GF(2^k)$

- On the other hand, the DLP in the multiplicative group of  $GF(2^k)$  is also known to be rather easy (but not trivial)
- The multiplicative group of  $GF(2^k)$  consists of
  - The set  $S = GF(2^k) \{0\}$
  - The group operation multiplication mod p(x)
  - p(x) is the irreducible polynomial generating the field  $GF(2^k)$
  - The group order is  $2^k 1$
  - The group order is prime, when  $2^k 1$  is prime,

ttp://koclab.org Çetin Kaya Koç Winter 2017 6

# Discrete Logarithms in $GF(2^k)$

- $\bullet$  Consider the multiplicative group of  $GF(2^3)$
- The set is  $S = \{1, x, x + 1, x^2, x^2 + 1, x^2 + x, x^2 + x + 1\}$
- The operation is the multiplication mod  $p(x) = x^3 + x + 1$
- The group order is 7, which happens to be prime
- Thus, all elements of the set is primitive, except 1
- Let us take g = x
- The powers  $x^i$  for  $i=1,2,\ldots,7$  generates all elements of the set S

$$\{x^i \pmod{p(x)} \mid i = 1, 2, \dots, 7\} =$$
  
 $\{x, x^2, x + 1, x^2 + x, x^2 + x + 1, x^2 + 1, 1\}$

http://koclab.org Çetin Kaya Koç Winter 2017 7 / 58

# Discrete Logarithms in $GF(2^k)$

• Consider the DLP in GF(2<sup>3</sup>)

$$x^a = x^2 + x \pmod{x^3 + x + 1}$$

where a is the unknown, to be computed (the DL)

- Which power of x is equal to  $x^2 + x \pmod{x^3 + x + 1}$ ?
- We can solve this particular DLP using exhaustive search
- There are 7 candidates for a, and we find it as a = 4
- The general DLP seems difficult
- Don Coppersmith proved that it is easy (but not trivial)

http://koclab.org Cetin Kaya Koc Winter 2017 8 /

# Exponentiation and Discrete Logarithms in $\mathcal{Z}_p^*$

- Consider the multiplicative group  $\mathcal{Z}_p^*$  of integers modulo a prime p and a primitive element  $g \in \mathcal{Z}_p^*$
- ullet The exponentiation operation is the computation of y in

$$y = g^x = \overbrace{g \cdot g \cdots g}^{x \text{ terms}} \pmod{p}$$

for a positive integer x

- The discrete logarithm problem in this group is defined to be the computation of x, given y, g, and p
- Example: Given p = 23 and g = 5, find x such that

$$11 = 5^x \pmod{23}$$

Answer: x = 9

- (ロ) (部) (注) (注) (注) ( つ) (P

# Discrete Logarithms in $\mathcal{Z}_p^*$

• Given  $p = 158(2^{800} + 25) + 1 =$  1053546280395016975304616582933958731948871814925913489342 6087342587178835751858673003862877377055779373829258737624 5199045043066135085968269741025626827114728303489756321430 0237166369174066615907176472549470083113107138189921280884 003892629359

and 
$$g=17$$
, find  $x\in\mathcal{Z}_p^*$  such that

$$2=17^{x}\pmod{p}$$

Answer: ?

◆ロト ◆御 ト ◆ 差 ト ◆ 差 ・ 釣 へ ②

#### Discrete Logarithm Notation

- The computation of x in  $y = g^x \pmod{p}$  is called the DLP
- Here x is equal to the discrete analogue of the logarithm

$$x = \log_g y \pmod{p-1}$$

- The modulus is p-1 since the powers are added and multiplied mod p-1 according to Fermat's Theorem
- The logarithm notation is particularly useful
- For example,  $2^{15} = 27 \pmod{29}$  implies

$$\log_2 27 = 15 \pmod{28}$$

11 / 58

http://koclab.org Cetin Kaya Koc

#### Discrete Logarithm Notation

- The logarithm notation allows us to compute new discrete logarithms
- For example

$$\log_g(a \cdot b \bmod p) = \log_g a + \log_g b \pmod{p-1}$$

Similarly

$$\log_g(a^e \cdot b^f \bmod p) = e \cdot \log_g a + f \cdot \log_g b \pmod{p-1}$$

◆ロト ◆回 ト ◆ 直 ト ◆ 直 ・ り へ ○

ttp://koclab.org Çetin Kaya Koç Winter 2017 12 / 58,

### Discrete Logarithm Notation

For example,

$$2^{15} = 27 \pmod{29}$$
  
 $2^{22} = 5 \pmod{29}$ 

This implies

$$\log_2 27 = 15 \pmod{28}$$
  
 $\log_2 5 = 22 \pmod{28}$ 

We can now write

$$\log_2 27 + \log_2 5 = \log_2 (27 \cdot 5 \mod 29) \pmod{28}$$
$$= \log_2 19 \pmod{28}$$
$$15 + 22 = 9 \pmod{28}$$

• Therefore:  $\log_2 19 = 9 \pmod{28} \Rightarrow 2^9 = 19 \pmod{29}$ 

http://koclab.org Çetin Kaya Koç Winter 2017 13 / 58

#### Exhaustive Search

• Since  $x \in \mathcal{Z}_p^*$ , we can perform search, and try all possible values of x:

for 
$$i = 1$$
 to  $p - 1$   
 $z = g^i \pmod{p}$   
if  $y = z$   
return  $x = i$ 

• This algorithm computes ith power of g mod p at each step

Winter 2017

14 / 58

#### **Exhaustive Search**

ullet The *i*th power of g need not be computed from scratch at each step

$$z = g$$
for  $i = 2$  to  $p - 1$ 

$$z = g \cdot z \pmod{p}$$
if  $y = z$ 

$$\text{return } x = i$$

- This algorithm requires p-2 multiplications
- The multiplications of k-bit operands are of order  $O(k^2)$
- The search complexity is exponential in k

$$O(pk^2) = O(2^k k^2)$$

- 4 ロ 2 4個 2 4 種 2 4 種 3 年 - 约 9 0 0

http://koclab.org Cetin Kaya Koç Winter 2017 15 / 58

### Shanks Algorithm

- In 1973, Shanks described an algorithm for computing discrete logarithms that runs in  $O(\sqrt{p})$  time and requires  $O(\sqrt{p})$  space
- Let  $y = g^x \pmod{p}$ , with  $m = \lceil \sqrt{p} \rceil$  and  $p < 2^k$
- Shanks' method is a deterministic algorithm and requires the construction of two tables S and T, which contains pairs of integers
- Due to the steps in Tables S and T, Shank algorithm is called Shank's Baby-Step-Giant-Step algorithm

(ロ) (레) (필) (필) (필) ( 필) ( 연Q)

16 / 58

#### Shanks Algorithm

• The construction of *S* is called the giant-steps:

$$S = \{(i, g^{i \cdot m}) \mid i = 0, 1, \dots, m\}$$

• The construction of T is called the baby-steps:

$$T = \{(j, y \cdot g^j) \mid j = 0, 1, \dots, m\}$$

We then search for an element that is in both S and T tables

◆□▶◆御▶◆巻▶◆巻▶ ● める@

tp://koclab.org Çetin Kaya Koç Winter 2017 17 / 58

18 / 58

### Shanks Algorithm

• The existence of the same group element in both tables implies

$$g^{i \cdot m} = y \cdot g^j = g^x \cdot g^j = g^{x+j} \pmod{p}$$

• We get the indices i and i, and write the equality of the powers as

$$i \cdot m = x + j \pmod{p-1}$$

- and thus find  $x = i \cdot m j \pmod{p-1}$
- To use this method in practice, one would typically only store the giant-steps array and the lookup each successive group element from the baby-steps array until a match is found
- Obviously, the algorithm requires enormous amount of space

Cetin Kaya Koc Winter 2017

- Consider the solution of  $y = 44 = 3^x \pmod{101}$
- $m = \lceil \sqrt{101} \rceil = 11$ , therefore, the giant-steps and baby-steps tables:

• The solution  $x = 4 \cdot 11 - 9 = 35$ , i.e.,  $3^{35} = 44 \pmod{101}$ 

4 🗆 🖟 4 🖆 🖟 4 🖹 7 4 🖹 7 4 🖹 7 9 4 (\*\*

- Consider the solution of  $y = 1736 = 5^x \mod 2017$
- $m = \lceil \sqrt{2017} \rceil = 45$
- ullet The S table is produced using  $S_i=5^{mi} mod 2017$  for  $i=0,1,\ldots,45$

- There exists a group element in both tables: 438
- The indices of 438 in S and T table are i = 28 and j = 26
- Also, we have m = 45, g = 5, and p = 2017
- The equality  $g^{i \cdot m} = y \cdot g^j \pmod{p}$  yields the discrete log of y

$$g^{28\cdot45} = 1736 \cdot g^{26} \pmod{2017}$$
  
 $\log_5(g^{28\cdot45}) = \log_5(1736) + \log_5(g^{26}) \pmod{2016}$   
 $28\cdot45 = x + 26 \pmod{2016}$   
 $x = 28\cdot45 - 26 \pmod{2016}$   
 $= 1234$ 

• Indeed,  $5^{1234} = 1736 \pmod{2017}$ 

#### Correctness of Shanks Algorithm

- Solving for x in  $y = g^x \pmod{p}$  requires creation of 2 tables of  $O(\sqrt{p})$  size
- However, x can be any one of the numbers in the set [2, p-2], which is of size O(p)
- How does it work that by searching in 2 tables of size  $O(\sqrt{p})$  we can find an element x that belongs to a set of size O(p)?

<ロ > ← □

http://koclab.org Çetin Kaya Koç Winter 2017 23 / 58

# Proof of Correctness of Shanks Algorithm

• Since  $m = \lceil \sqrt{p} \rceil$ , we can write x in base-m as

$$x = i \cdot m + j$$

such that  $i, j \in [0, m-1]$ 

• For example, for p = 101, m = 11, and x = 35, we can write:

$$35 = 3 \cdot 11 + 2$$

• Instead of searching for  $x \in [2, p-2]$ , we search for  $i, j \in [0, m-1]$

http://koclab.org Çetin Kaya Koç Winter 2017 24 / 58

# Proof of Correctness of Shanks Algorithm

- Therefore, we would be performing 2 searches in two sets of size  $O(m) = O(\sqrt{p})$ , one search for i and the other for j
- The exponentiation equality is given as

$$y = g^{i \cdot m + j} \pmod{p}$$

This implies

$$y \cdot g^{-j} = g^{i \cdot m} \pmod{p}$$

4ロト 4回 ト 4 直 ト 4 直 ト 9 Q ○

tp://koclab.org Çetin Kaya Koç Winter 2017 25 / 58

# Proof of Correctness of Shanks Algorithm

- We would create one table (S) of values  $(i, g^{i \cdot m})$ , and another table (T) of values  $(j, y \cdot g^{-j})$
- An equality of the form

$$g^{i \cdot m} = y \cdot g^{-j} = g^x \cdot g^{-j} \pmod{p}$$

for particular values of i, j implies that

$$i \cdot m = x - j \pmod{p-1}$$

which allows us to compute x by creating 2 tables of size  $O(\sqrt{p})$ 

◆ロト ◆団 ト ◆ 豊 ト ◆ 豊 ・ り へ ○

http://koclab.org Cetin Kaya Koç Winter 2017 26 / 58

- Pollard Rho algorithm is also of  $O(\sqrt{p})$  time complexity, however, it does not require a large table
- It forms a pseudorandom sequence of elements from the group, and searches for a cycle to appear in the sequence
- The sequence is defined deterministically and each successive element is a function of only the previous element
- If a group element appears a second time, every element of the sequence after that will be a repeat of elements in the sequence
- According to the birthday problem, a cycle should appear after  $O(\sqrt{p})$  elements of the sequence have been computed

4ロト 4回ト 4 差ト 4 差ト 差 かなべ

http://koclab.org Çetin Kaya Koç

The Pollard Rho algorithm defines the sequence

$$a_{i+1} = \begin{cases} y \cdot a_i & \text{for } a_i \in S_0 \\ a_i^2 & \text{for } a_i \in S_1 \\ g \cdot a_i & \text{for } a_i \in S_2 \end{cases}$$

where  $S_0$ ,  $S_1$ , and  $S_2$  are disjoint partitions of the group elements, that are approximately the same size

- The initial term is taken as  $a_0 = g^{\alpha}$  for a random  $\alpha$
- Apparently, there is no need to keep all of the group elements
- We compute the sequences from a<sub>i</sub> to a<sub>2i</sub> until an equality is discovered
- The equality of two terms in the sequence implies equality on exponents mod (p-1), from which we solve for x

http://koclab.org Cetin Kaya Koc Winter 2017 28 / 58

- Consider the solution of  $y = 44 = 3^x \pmod{101}$
- We divide the set  $S = \{1, 2, \dots, 100\}$  into 3 sets such that  $S_0 = \{1, 2, \dots, 33\}, S_1 = \{34, 35, \dots, 66\}, \text{ and }$  $S_2 = \{67, 68, \dots, 100\}$
- We start with  $a_0 = g^{\alpha} \pmod{p}$  for a random  $\alpha$
- Taking  $\alpha = 15$ , we obtain  $a_0 = 3^{15} = 39 \pmod{101}$ ,
- The following terms of the iteration are obtained as

i	a <sub>i</sub>	$S_0$	$S_1$	$S_2$	powers of $y \& g$
	$a_0 = 39$		39		0 & 15
1	$a_1 = a_0^2 = 39^2 = 6$	6			0 & 30
	$a_2 = y \cdot a_1 = 44 \cdot 6 = 62$		62		1 & 30
3	$a_3 = a_2^2 = 62^2 = 6$	6			2 & 60
	$a_4 = y \cdot a_3 = 44 \cdot 6 = 62$		62		3 & 60
5	$a_5 = a_4^2 = 62^2 = 6$	6			6 & 120

Winter 2017 29 / 58

- Therefore, we find  $a_1 = a_3$ , and also  $a_2 = a_4$  and  $a_3 = a_5$
- The discovery of an equality in the sequence implies that we found a relationship between the exponent x and known powers of g
- The equality  $a_1 = a_3$  implies

$$y^0 \cdot g^{30} = y^2 \cdot g^{60} = (g^x)^2 \cdot g^{60} = g^{2x+60}$$

We have an equality over the exponents

$$30 = 2x + 60 \pmod{100} \rightarrow 2x = 70 \pmod{100}$$

- Since  $gcd(2,100) \neq 1$ , this equation has two solutions:  $x = \{35,85\}$
- We can check each candidate to verify:

$$3^x \stackrel{?}{=} 44 \pmod{100}$$

• We see that x = 35 is a solution since  $3^{35} = 44 \pmod{101}$ 

http://koclab.org Cetin Kaya Koc Winter 2017 30 / 58

• Similarly,  $a_2 = a_4$  implies

$$x + 30 = 3x + 60 \pmod{100} \rightarrow 2x = 70 \pmod{100}$$

- Therefore, the same set of solutions:  $x = \{35, 85\}$
- On the other hand, the equality of  $a_3 = a_5$  gives a different equation:

$$2x + 60 = 6x + 120 \pmod{100} \rightarrow 4x = 40 \pmod{100}$$

- We find 4 candidates:  $x = \{10, 35, 60, 85\}$
- By trying each one, we find the solution x = 35

- 4 ロ b 4 個 b 4 種 b 4 種 b 9 Q ()

31 / 58

http://koclab.org Çetin Kaya Koç Winter 2017

# Partitioning of S

• Another way to partition  $S = \{1, 2, \dots, p-1\}$ :

$$S_0 = \{a \in S \text{ and } a = 0 \pmod{3}\}\$$
  
 $S_1 = \{a \in S \text{ and } a = 1 \pmod{3}\}\$   
 $S_2 = \{a \in S \text{ and } a = 2 \pmod{3}\}\$ 

• For p = 101, we get  $S_0 = \{3, 6, 9, 12, \dots, 99\}$   $S_1 = \{1, 4, 7, 10, 13, \dots, 100\}$   $S_2 = \{2, 5, 8, 11, 14, \dots, 98\}$ 

 There could be different ways to partition, resulting in possibly different (randomized) timings for the Pollard Rho Algorithm

◆ロト ◆団ト ◆豆ト ◆豆ト □ りへ○

32 / 58

#### An Example of Pollard Rho Algorithm

- Consider the solution of  $y = 48 = 3^x \pmod{101}$
- ullet We partition  $S_j=\{a\mid a\in S \ {\sf and} \ a=j \ ({\sf mod}\ 3)\}$  for j=0,1,2
- We start with  $a_0 = g^{\alpha} \pmod{p}$  for a random  $\alpha$
- Taking  $\alpha = 10$ , we obtain  $a_0 = 3^{10} = 65 \pmod{101}$ ,
- The following terms of the iteration are obtained as

i	a <sub>i</sub>	$S_0$	$S_1$	$S_2$	powers of $y \& g$
0	$a_0 = 65$			65	0 & 10
	$a_1 = g \cdot a_0 = 3 \cdot 65 = 94$		94		0 & 11
2	$a_2 = a_1^2 = 94^2 = 49$		49		0 & 22
3	$a_3 = a_2^{\overline{2}} = 49^2 = 78$	78			0 & 44
4	$a_4 = y \cdot a_3 = 48 \cdot 78 = 7$		7		1 & 44
5	$a_5 = a_4^2 = 7^2 = 49$		49		2 & 88

tttp://koclab.org Cetin Kaya Koc Winter 2017 33 / 58

### An Example of Pollard Rho Algorithm

• The equality of  $a_2 = a_5$  implies

$$g^{22} = y^2 \cdot g^{88} = g^{2x} \cdot g^{88} \pmod{101}$$

From which, we write

$$2x + 88 = 22 \pmod{100}$$
  
 $2x = 34 \pmod{100}$ 

- We find candidates for the solution as {17,67}
- Trying both, we find x = 17 as the solution in  $3^x = 48 \pmod{101}$

http://koclab.org Çetin Kaya Koç Winter 2017 36 /

#### Another Example of Pollard Rho Algorithm

Since 710 appears twice in the 0th and 10th rows, we have

$$y^0 \cdot g^{27} = y^{13} \cdot g^{113} = g^{13x} \cdot g^{113} \pmod{2017}$$

• Therefore, from the powers of y and g we obtain

$$0 + 27 = 13 \cdot x + 113 \pmod{2016}$$

This gives x as

$$x = 13^{-1} \cdot (27 - 113) \pmod{2016}$$
  
= 1861 \cdot 1930 \quad \text{(mod 2016)}  
= 1234

 $\bullet$  This is the correct answer, since  $5^{1234} = 1736 \pmod{2017}$ 

http://koclab.org Cetin Kaya Koc Winter 2017 37 / 58

# The Complexity of Pollard Rho Algorithm

- The Pollard Rho algorithm generates a sequence in order to find a match, due to the birthday problem
- Its time complexity is  $O(\sqrt{p})$  which is exponential in terms of the input size in bits:  $O(2^{k/2})$
- However, there are subexponential algorithms, for example the index calculus method for the group  $\mathcal{Z}_p^*$  has subexponential time complexity
- Before that, let us study the Pohlig-Hellman algorithm which converts on order-ab DL into an order-a DL, an order-b DL, and a few exponentiations

ttp://koclab.org Cetin Kaya Koç Winter 2017 38 / 58

# Pohlig-Hellman Algorithm

- The group order in  $(Z_p^*, * \text{mod } p)$  is p-1
- There are p-1 elements in the set  $Z_p^* = \{1, 2, \dots, p-1\}$
- Assume  $p-1=a\cdot b$ , that is, g has order  $a\cdot b$
- Given y, which is a power of g, we deduce that:  $g^a$  has order b since  $(g^a)^b = g^{ab} = g^{p-1} = 1$  $g^b$  has order a since  $(g^b)^a = g^{ab} = g^{p-1} = 1$  $y^a$  is a power of  $g^a$  since  $y^a = (g^x)^a = (g^a)^x$

http://koclab.org Cetin Kaya Koc 39 / 58

#### Pohlig-Hellman Algorithm

• Step 1: Solve for *r* in the DLP:

$$(g^a)^r = y^a \pmod{p}$$

Step 2: Solve for s in the DLP:

$$(g^b)^s = y \cdot g^{-r} \pmod{p}$$

- Step 3: Compute  $x = r + s \cdot b$
- Correctness proof:

$$g^{r+s \cdot b} = g^r \cdot (g^s)^b \pmod{p}$$
  
=  $g^r \cdot y \cdot g^{-r} \pmod{p}$   
=  $y$ 

10710712712712712

#### An Example of Pohlig-Hellman Algorithm

• Consider p = 1259 and g = 2, and the DLP

$$y = g^x \pmod{p} \rightarrow 338 = 2^x \pmod{1259}$$

- $p 1 = 34 \cdot 37 = a \cdot b$
- Step 1: Solve for r in

$$(g^a)^r = y^a \pmod{1259}$$
  
 $(2^{34})^r = 338^{34} \pmod{1259}$   
 $870^r = 463 \pmod{1259}$ 

- Since 870 is of order b = 37, we solve a smaller DLP
- The solution r is in the set [0, b-1] = [0, 36]
- It can be found using exhaustive search
- The solution is r = 27 since  $870^{27} = 463 \mod 1259$

http://koclab.org Cetin Kaya Koc Winter 2017 41 / 58

# An Example of Pohlig-Hellman Algorithm

Step 2: Solve for s in the DLP:

$$(g^b)^s = y \cdot g^{-r} \pmod{1259}$$
  
 $(2^{37})^s = 338 \cdot 2^{-27} \pmod{1259}$   
 $665^s = 338 \cdot 880 \pmod{1259}$   
 $665^s = 316 \pmod{1259}$ 

- This is also a smaller DLP, since s is in the set [0, a 1] = [0, 33]
- We find s = 2 using exhaustive search:  $665^2 = 316 \mod 1259$
- Step 3: We find x as

$$x = r + s \cdot b = 27 + 2 \cdot 37 = 101$$

• This is indeed the solution of DLP:  $2^{101} = 338 \mod 1259$ 

#### Another Example of Pohlig-Hellman Algorithm

• Consider p = 2017 and g = 5, and the DLP

$$y = g^x \pmod{p} \rightarrow 1736 = 5^x \pmod{2017}$$

- $p 1 = 2016 = 36 \cdot 56 = a \cdot b$
- Step 1: Solve for r in

$$(g^a)^r = y^a \pmod{p}$$
  
 $(5^{36})^r = 1736^{36} \pmod{2017}$   
 $995^r = 1695 \pmod{2017}$ 

- Since 995 is of order b = 56, we solve a smaller DLP
- The solution r is in the set [0, b-1] = [0, 55]
- It can be found using exhaustive search
- The solution is r = 2 since  $995^2 = 1695 \mod 2017$

http://koclab.org Cetin Kaya Koc Winter 2017 43 / 58

#### Another Example of Pohlig-Hellman Algorithm

• Step 2: Solve for *s* in the DLP:

$$(g^b)^s = y \cdot g^{-r} \pmod{p}$$
  
 $(5^{56})^s = 1736 \cdot 5^{-2} \pmod{2017}$   
 $665^s = 1736 \cdot 1775 \pmod{2017}$   
 $284^s = 1441 \pmod{2017}$ 

- This is also a smaller DLP, since s is in the set [0, a-1] = [0, 35]
- We find s = 22 using exhaustive search:  $284^{22} = 1441 \mod 2017$
- Step 3: We find x as

$$x = r + s \cdot b = 2 + 22 \cdot 56 = 1234$$

• This is indeed the solution of DLP:  $5^{1234} = 1736 \mod 2017$ 

http://koclab.org Çetin Kaya Koç Winter 2017 44 / 58

#### Complexity of the Pohlig-Hellman Algorithm

- The Pohlig-Hellman algorithm requires two independent DLPs which are order  $\sqrt{a}$  and  $\sqrt{b}$  when  $p=a\cdot b$
- These can be solved using exhaustive search, requiring  $O(\sqrt{a})$  and  $O(\sqrt{b})$  multiplications
- It works better if a or b factors even further
- The means, we can apply Pohlig-Hellman recursively
- If the largest prime divisor of p-1 is much smaller than p, then Pohlig-Hellman computes DL more quickly

# Applications to ECDLP

- The exhaustive search, Shank's, Pollard Rho, and Pohlig-Hellman algorithms are applicable to any group
- They do not require particular properties from the group, and perform only group operations to solve for the DLP
- They are applicable to the ECDLP
- They all require exponential time
- Given the DLP  $y=g^{\times}\pmod{p}$ , these algorithms require: Exhaustive Search: O(p) operations Shank's Baby-Step-Giant-Step:  $O(\sqrt{p})$  operations and  $O(\sqrt{p})$  space Pollard Rho:  $O(\sqrt{p})$  operations and probably less space Pohlig-Hellman:  $O(\sqrt{a}+\sqrt{b})$  for  $p-1=a\cdot b$

- We are attempting to solve the DLP  $y = g^x \pmod{p}$
- Consider the set S, called the factor base, the set of all primes less than or equal to some bound b
- For example,  $S = \{2, 3, 5\}$  where b = 5
- An element of  $Z_p^*$  is called smooth with respect to b, if all of its factors are contained in S
- For example, these elements of  $Z_{19}^*$  are smooth wrt b=5:

$$\{2, 3, 4 = 2^2, 5, 6 = 2 \cdot 3, 8 = 2^3, 9 = 3^2, 10 = 2 \cdot 5, 12 = 2^2 \cdot 3, 15 = 3 \cdot 5, 16 = 2^4, 18 = 2 \cdot 3^2\}$$

• These elements of  $Z_{10}^*$  are not smooth wrt b=5:

$$\{7, 11, 13, 14 = 2 \cdot 7, 17\}$$

- The Index Calculus algorithm has 3 steps
- Step 1: Take a random  $\alpha$ , and compute  $g^{\alpha} \pmod{p}$ , and see if it is smooth, that is

$$g^{\alpha} = \prod_{p_i \in S} p_i^{\alpha_i}$$

ullet If it is, we obtain its discrete logarithm base g, where all  $lpha_i$  are known

$$\alpha = \sum_{p_i \in S} \alpha_i \log_g p_i \pmod{p-1}$$

ullet Continue this process until more than |S| equations are known

- Step 2: Solve this system of equations to find the unique values for each of  $\log_{\sigma} p_i \pmod{p-1}$
- Step 3: In this step we find the solution to the DLP  $y = g^x \pmod{p}$ , that is we compute  $\log_{\rho} y \pmod{p-1}$
- Select a random  $\alpha$  so that  $y \cdot g^{\alpha} \pmod{p}$  is smooth
- When we find such an  $\alpha$ , we can compute x using

$$x = \log_g y = -\alpha + \sum_{p_i \in S} \alpha_i \log_g p_i \pmod{p-1}$$

where everything on the right hand side is known

- Consider p = 37, g = 5 and  $S = \{2, 3\}$
- Step 1: Try  $\alpha = 6$ :  $g^{\alpha} = 5^6 = 11 \pmod{37}$ : Not smooth
- Try  $\alpha = 7$ :  $g^{\alpha} = 5^7 = 18 = 2^1 \cdot 3^2 \pmod{37}$ : Smooth
- Thus, we find

$$1 \cdot \log_5 2 + 2 \cdot \log_5 3 = 7 \pmod{36}$$

- Try  $\alpha = 14$ :  $g^{\alpha} = 5^{14} = 28 = 2^2 \cdot 7 \pmod{37}$ : Not smooth
- Try  $\alpha = 31$ :  $g^{\alpha} = 5^{31} = 24 = 2^3 \cdot 3^1 \pmod{37}$ : Smooth
- Thus, we find

$$3 \cdot \log_5 2 + 1 \cdot \log_5 3 = 31 \pmod{36}$$

4 U P 4 dP P 4 E P 4 E P 4 E P 9 V ( V

http://koclab.org

Step 2: We solve these two equations

$$1 \cdot \log_5 2 + 2 \cdot \log_5 3 = 7 \pmod{36}$$
  
 $3 \cdot \log_5 2 + 1 \cdot \log_5 3 = 31 \pmod{36}$ 

Expressed in matrix form as

$$\begin{bmatrix} 1 & 2 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} \log_5 2 \\ \log_5 3 \end{bmatrix} = \begin{bmatrix} 7 \\ 31 \end{bmatrix} \pmod{36}$$

- We find the solutions as  $\log_5 2 = 11$  and  $\log_5 3 = 34$
- These are verified as  $5^{11} = 2 \pmod{37}$  and  $5^{34} = 3 \pmod{37}$

- 4 ロ b 4 個 b 4 き b 4 き b 9 Qで

http://koclab.org

- Step 3: Suppose we want to find log<sub>5</sub> 17 (mod 36)
- We are trying to solve the DLP:  $y = 17 = 5^x \pmod{37}$
- Try  $\alpha = 24$ :  $y \cdot g^{\alpha} = 17 \cdot 5^{24} = 35 \pmod{37}$ : Not smooth
- Try  $\alpha = 15$ :  $y \cdot g^{\alpha} = 17 \cdot 5^{15} = 12 \pmod{37}$ : Smooth
- This number factors as  $12 = 2^2 \cdot 3^1$ , thus, we find

$$\log_{g} y = -\alpha + \sum_{p_{i} \in S} \alpha_{i} \log_{g} p_{i} \pmod{p-1}$$

$$\log_{5} 17 = -15 + 2 \cdot \log_{5} 2 + 1 \cdot \log_{5} 3 \pmod{36}$$

$$= -15 + 2 \cdot 11 + 1 \cdot 34 \pmod{36}$$

$$= 41 \pmod{36}$$

$$= 5$$

• The solution is x = 5 in  $17 = 5^x \pmod{37}$ , since  $5^5 = 17 \pmod{37}$ 

http://koclab.org Çetin Kaya Koç Winter 2017 53 / 58

- Step 3: Suppose we want to find log<sub>5</sub> 19 (mod 36)
- We are trying to solve the DLP:  $y = 19 = 5^x \pmod{37}$
- Try  $\alpha = 5$ :  $y \cdot g^{\alpha} = 19 \cdot 5^5 = 27 \pmod{37}$ : Smooth
- This number factors as  $27 = 3^3$ , thus, we find

$$\log_{g} y = -\alpha + \sum_{p_{i} \in S} \alpha_{i} \log_{g} p_{i} \pmod{p-1}$$

$$\log_{5} 19 = -5 + 3 \cdot \log_{5} 3 \pmod{36}$$

$$= -5 + 3 \cdot 34 \pmod{36}$$

$$= 97 \pmod{36}$$

$$= 25$$

• Thus x = 25 in  $19 = 5^x \pmod{37}$ , since  $5^{25} = 19 \pmod{37}$ 

- Consider p = 2017, g = 5 and  $S = \{2, 3, 7, 11\}$
- Try  $\alpha = 130$ :  $g^{\alpha} = 5^{130} = 1078 = 2^1 \cdot 7^2 \cdot 11^1 \pmod{2017}$ :
- Equation:  $\log_5(2) + 2\log_5(7) + \log_5(11) = 130 \pmod{2016}$
- Try  $\alpha = 1874$ :  $g^{\alpha} = 5^{1874} = 42 = 2^1 \cdot 3^1 \cdot 7^1 \pmod{2017}$ :
- Equation:  $\log_5(2) + \log_5(3) + \log_5(7) = 1874 \pmod{2016}$
- Try  $\alpha = 1130$ :  $g^{\alpha} = 5^{1130} = 1617 = 3^1 \cdot 7^2 \cdot 11^1 \pmod{2017}$ :
- Equation:  $\log_5(3) + 2\log_5(7) + \log_5(11) = 1130 \pmod{2016}$
- Try  $\alpha = 1820$ :  $g^{\alpha} = 5^{1820} = 1694 = 2^1 \cdot 7^1 \cdot 11^2 \pmod{2017}$ :
- Equation:  $\log_5(2) + \log_5(7) + 2\log(11) = 1820 \pmod{2016}$

ttp://koclab.org Cetin Kaya Koc Winter 2017 55 / 58

Linear system of equations

$$\begin{bmatrix} 1 & 0 & 2 & 1 \\ 1 & 1 & 1 & 0 \\ 0 & 1 & 2 & 1 \\ 1 & 0 & 1 & 2 \end{bmatrix} \begin{bmatrix} \log_5(2) \\ \log_5(3) \\ \log_5(7) \\ \log_5(11) \end{bmatrix} = \begin{bmatrix} 130 \\ 1874 \\ 1130 \\ 1874 \end{bmatrix} \pmod{2016}$$

- The determinant of the matrix mod 2016 is equal to 5
- This implies that the above matrix is invertible mod 2016
- The inverse matrix mod 2016 and the solution is found as

$$\begin{bmatrix} 1613 & 807 & 1209 & 1613 \\ 1612 & 807 & 1210 & 1613 \\ 807 & 403 & 1613 & 806 \\ 806 & 403 & 1613 & 807 \end{bmatrix} \begin{bmatrix} 130 \\ 1874 \\ 1130 \\ 1874 \end{bmatrix} = \begin{bmatrix} 30 \\ 1030 \\ 814 \\ 488 \end{bmatrix} = \begin{bmatrix} \log_5(2) \\ \log_5(3) \\ \log_5(7) \\ \log_5(11) \end{bmatrix}$$

THE PROPERTY OF THE

http://koclab.org Çetin Kaya Koç Winter 2017

• These discrete logs are easily verified:

- Finding  $x = \log_5(1736) \mod 2016$
- Select  $\alpha = 1188$ , which gives  $y \cdot g^{\alpha} \pmod{p}$  as

$$1736 \cdot 5^{1188} = 1848 = 2^3 \cdot 3^1 \cdot 7^1 \cdot 11^1 \text{ mod } 2017$$

- Therefore:  $\log_5(1736 \cdot 5^{1188}) = \log_5(2^3 \cdot 3^1 \cdot 7^1 \cdot 11^1) \mod 2016$
- We obtain

$$\log_5(1736) + 1188 = 3\log_5(2) + \log_5(3) + \log_5(7) + \log_5(11) \mod 2016$$
  
 $\log_5(1736) = -1188 + 3 \cdot 30 + 1030 + 814 + 488 \mod 2016$   
 $= 1234$ 

Winter 2017 57 / 58 Cetin Kaya Koc

# Complexity of the Index Calculus Algorithm

- Analysis of the Index Calculus Algorithm depends on several factors:
  - Likelihood that  $g^{\alpha} \pmod{p}$  and  $y \cdot g^{\alpha} \pmod{p}$  smooth
  - ullet The chance that |S| equations are linearly independent  $\pmod{p-1}$
  - Solutions of the linear equations  $\pmod{p-1}$
- The time complexity of the Index Calculus Algorithm is found as

$$O\left(e^{c\sqrt[3]{(\log p)(\log\log p)^2}}\right)$$

- The time complexity is sub-exponential since it is faster than exponential (in log p) but slower than polynomial
- Compare this to the Pollard Rho algorithm:  $O(\sqrt{p})$

4日 > 4団 > 4 豆 > 4 豆 > 1 豆 の Q O
