

Lecture 4 SVT, Linear Query Release (Part II) and Private Selection

Yu-Xiang Wang

COMPUTER SCIENCE

UC SANTA BARBARA

Computing. ReInvented.

Recap: last lecture

- Generalizing the problem of linear query release

$$\frac{1}{n} \sum_{i=1}^n f(\phi_i) = \frac{1}{n} \langle q_f, x \rangle$$

$$q_1, \dots, q_k \in [0, 1]^{|X|}$$

- Apply Laplace mechanism to this problem

- Releasing queries
- Releasing data (i.e., contingency table)

$$\text{error} \leq \left(\frac{1}{n} \right) \frac{k \log \frac{k}{\delta}}{\epsilon} \quad \text{Lap. } 1-\delta$$

$$\hat{X} = X + \text{lap}\left(\frac{1}{\epsilon}\right)$$

$$\left| \frac{1}{n} (q_i^T \hat{X} - q_i^T X) \right| \leq \frac{\sqrt{|X|} \log \frac{k}{\delta}}{n \epsilon} \quad \text{Lap. } 1-\delta$$

- Sparse vector technique

- Privately selecting an sparse number of queries that are interesting among possibly infinitely many queries

Recap: (Generalized) AboveThreshold mechanism

Algorithm 1 Input is a private database D , an adaptively chosen stream of sensitivity 1 queries f_1, \dots , and a threshold T . Output is a stream of responses a_1, \dots

AboveThreshold($D, \{f_i\}, T, \epsilon$)

Let $\hat{T} = T + \text{Lap}\left(\frac{2}{\epsilon}\right)$.
for Each query i do

Let $\nu_i = \text{Lap}\left(\frac{4}{\epsilon}\right)$
if $f_i(D) + \nu_i \geq \hat{T}$ then
Output $a_i = \top$.

Halt.

else

Output $a_i = \perp$.

end if

end for

Any noise-adding mechanism M_1 satisfying $\epsilon/2$ -DP for queries with sensitivity 1.

Any noise-adding mechanism M_2 satisfying $\epsilon/2$ -DP for queries with sensitivity 2.

Recap: SparseVector mechanism

1. Start with a budget of ϵ , and a maximum number of “discoveries” c
2. Split ϵ into c equal parts and run **AboveThreshold** for up to c times, each with a privacy budget of ϵ/c .
3. Stop when either the stream of queries are exhausted or if all c discoveries are made.

Recap: the analysis of AboveThreshold

1. The output space of the algorithm

$$\{\perp^k \top \mid k = 0, 1, \dots, \infty\}$$

- The output can be completely described by a random integer k

2. w.l.o.g., we can assume $T = 0$ (why?)

3. The probability of outputting k is

$$\begin{aligned} \Pr[\mathcal{M}(D) = k] &= \mathbb{E}_{z \sim p_\rho} [\Pr[\mathcal{M}(D) = k | z]] \\ &= \mathbb{E}_{z \sim p_\rho} \left[\prod_{i \leq k} \Pr[q_i(D) + \nu_i < z | z] \Pr[q_{k+1}(D) + \nu_i \geq z | z] \right] \\ &= \int_{-\infty}^{+\infty} p_\rho(z) \left(\prod_{i \leq k} \int_{-\infty}^{z - q_i(D)} p(\nu_i) d\nu_i \right) \cdot \int_{z - q_{k+1}(D)}^{\infty} p(\nu_{k+1}) d\nu_{k+1} dz \end{aligned}$$

Recap: The analysis of AboveThreshold

$$\begin{aligned}
 \Pr[\mathcal{M}(D) = k] &= \mathbb{E}_{z \sim p_\rho} [\Pr[\mathcal{M}(D) = k | z]] \\
 &= \mathbb{E}_{z \sim p_\rho} \left[\prod_{i \leq k} \Pr[q_i(D) + \nu_i < z | z] \Pr[q_{k+1}(D) + \nu_i \geq z | z] \right] \\
 &= \int_{-\infty}^{+\infty} p_\rho(z) \left(\prod_{i \leq k} \int_{-\infty}^{z - q_i(D)} p(\nu_i) d\nu_i \right) \cdot \int_{z - q_{k+1}(D)}^{\infty} p(\nu_{k+1}) d\nu_{k+1} dz
 \end{aligned}$$

Key trick: a change of variable that shifts noisy-threshold by Δ

$$\begin{aligned}
 &\stackrel{u := z + \Delta}{=} \int_{-\infty}^{+\infty} p_\rho(u - \Delta) \left(\prod_{i \leq k} \int_{-\infty}^{u - \Delta - q_i(D)} p(\nu_i) d\nu_i \right) \cdot \int_{u - \Delta - q_{k+1}(D)}^{\infty} p(\nu_{k+1}) d\nu_{k+1} du \\
 &= \int_{-\infty}^{+\infty} p_\rho(u) \left(\frac{p_\rho(u - \Delta)}{p_\rho(u)} \right) \left(\prod_{i \leq k} \int_{-\infty}^{u - \Delta - q_i(D)} p(\nu_i) d\nu_i \right) \cdot \int_{u - \Delta - q_{k+1}(D)}^{\infty} p(\nu_{k+1}) d\nu_{k+1} du \\
 &= \mathbb{E}_{z \sim p_\rho} \left[\left(\frac{p_\rho(z - \Delta)}{p_\rho(z)} \right) \left(\prod_{i \leq k} \int_{-\infty}^{z - \Delta - q_i(D)} p(\nu_i) d\nu_i \right) \cdot \int_{z - \Delta - q_{k+1}(D)}^{\infty} p(\nu_{k+1}) d\nu_{k+1} \right]
 \end{aligned}$$

$$\Pr(z = z - \Delta) = \Pr(z + \Delta = z)$$

$$\Pr(z = z) = \Pr(0 + z = z)$$

$$\Pr(\nu_i \leq z - \Delta - q_i(D))$$

$$\Pr(\nu_i + q_i(D) + \Delta \leq z) \leq \Pr(\nu_i + q_i(D) \leq z)$$

$$e^{\epsilon} \Pr(q_i(D) \geq z)$$

Recap: Bounding the third term via a fictitious query

$$\int_{z-\Delta-q_{k+1}(D)}^{\infty} p(\nu_{k+1}) d\nu_{k+1} \quad \overset{?}{\longleftrightarrow} \quad \int_{z-q_{k+1}(D')}^{\infty} p(\nu_{k+1}) d\nu_{k+1}$$

$\Pr[V_{k+1} \geq z - \Delta - q_{k+1}(D)] \leq e^{-\epsilon} \Pr[q_{k+1}(D') + V_{k+1} \geq z]$

- Define: $\tilde{q}(\tilde{D}) = \begin{cases} q_{k+1}(D) + \Delta, & \text{if } \tilde{D} = D \\ q_{k+1}(\tilde{D}), & \text{otherwise.} \end{cases}$

- What is the sensitivity of \tilde{q} ? $\geq \Delta$

V_{k+1}

$\forall k$

$$P(M(D)=k) \leq e^{-\epsilon} P(M(D')=k)$$

This lecture

- Finish the topic on SVT
- Apply SVT for answering many linear queries
 - Private-Multiplicative Weight
- Differentially private selection
 - Exponential mechanism
 - Report Noisy Max

Readings

- For private multiplicative weights algorithm
 - Dwork and Roth, Section 4.2.
 - Alternatively, Vadhan: Section 4.2
- For a proof of the multiplicative weight / hedge
 - [Online Convex Optimization book](#) (Hazan), Section 1.3
 - Or watch my video from [Convex Optimization](#) (taught in 2020 Spring, will post the link on Piazza)
- For private selection, read:
 - Dwork and Roth Section 3.3 and 3.4
 - **[Advanced reading]** Dong's blog on exponential mechanism
<https://dongjs.github.io/2020/02/10/ExpMech.html>

$$P(|\text{lap}(b)| > t) \leq e^{-\frac{t}{b}}$$

Utility of SparseVector

$$C \cdot \text{lap R.V.} \left(\frac{2C}{\epsilon} \right)$$

$$K \cdot \text{lap R.V.} \left(\frac{4C}{\epsilon} \right)$$

$$\text{Error} \leq \frac{4C}{\epsilon} \log \frac{2K}{\delta}$$

- Idea is to simply bound the magnitude of the noise Wp/s
 - (All true discoveries.) With high probability, we do not wrongly reject interesting queries.

$$q_i^T x + V_j \geq T + \epsilon$$

for all those we output T

$$q_i^T x > T - \frac{\delta C}{\epsilon} \log \frac{2K}{\delta}$$

- (No-false discovery). With high probability, we also do not wrongly identify queries that are not interesting as interesting. for all those i when output = \perp

$$q_i^T x + V_j < T + \epsilon$$

$$q_i^T x < T + \frac{\delta C}{\epsilon} \log \frac{2K}{\delta}$$

- Union bound over all of them.

We are outputting only the selections,
but not numerical values? NumericSparse!

- This is trivial to fix with twice the privacy budget.
- Compose the following:
 - AboveThresh1, LapMech1, AboveThresh2, LapMech2,...
- Each one of the mechanism is **adaptively chosen** based on realized previous outcomes.
 - How does LapMech_j depend on the output of AboveThresh_j?
 - How does the AboveThresh_j depend on all previous outputs?

Let's apply the above SVT method for online query release.

- Problem setup:

- A adaptive online sequence of linear queries.
- The curator has to answer them as they arrive.

q_1, q_2, \dots, q_k

$q_i: (q_{i,1}, q_{i,2}, \dots, q_{i,1}, q_{i,1})$

q_1, q_2, \dots, q_k

- Baseline:

- Laplace mechanism for releasing queries $O(|Q| / \epsilon)$
- Laplace mechanism for releasing contingency table $O(\sqrt{|X|} \log |Q| / \epsilon)$.

- Question: Is it possible to get $O(\text{polylog}(|Q|, |X|))$ error?

Idea: Use **correlated noise** by learning a synthetic dataset

Synthetic
X
Active
X

- We will be using sparse vector technique!
- For an online sequence of queries $\frac{|q^T x - q^T \tilde{x}|}{\alpha} > \alpha$
 - Continue to run "AboveThreshold", if error is below a noise threshold
 - Return what the synthetic data set returns
 - else: Release the query using Laplace Mechanism
 - Update the synthetic data
 - Restart "AboveThreshold"

Detour: No-regret online learning from expert advice

	Dan	Ming	Rachel	Raffles
Day 1	ASIA	Coob	FB	CNE
Day 2	19.	-2%	5%	4%

D.T

- N experts, each give advices on stock choices
- After each day, their losses are revealed
- Can I come up with a strategy that does as well as the best expert with **(asymptotically) no regret?**

• Define **“Regret”**:

$$X_1, \dots, X_T \in \Delta^4, \quad l_t \in [0, 1]^4$$

$$\sum_{t=1}^T \langle X_t, l_t \rangle \quad \uparrow \quad \text{my loss}$$

$$\min_i \sum_{t=1}^T l_t[i] = \underline{O(\sqrt{T})}$$

↑
loss of the best expert.

Multiplicative Weights Algorithm (i.e., the Hedge algorithm)

Algorithm 1 Hedge

- 1: Initialize: $\forall i \in [N], W_1(i) = 1$
 - 2: **for** $t = 1$ to T **do**
 - 3: Pick $i_t \sim_R W_t$, i.e., $i_t = i$ with probability $\mathbf{x}_t(i) = \frac{W_t(i)}{\sum_j W_t(j)}$
 - 4: Incur loss $\ell_t(i_t)$. *, $\ell_t(\mathbf{x}_t) = \ell_t^\top \mathbf{x}_t$*
 - 5: Update weights $W_{t+1}(i) = W_t(i) e^{-\varepsilon \ell_t(i)}$
 - 6: **end for**
-

Theorem 1.5. Let ℓ_t^2 denote the N -dimensional vector of square losses, i.e., $\ell_t^2(i) = \ell_t(i)^2$, let $\varepsilon > 0$, and assume all losses to be non-negative. The Hedge algorithm satisfies for any expert $i^* \in [N]$:

$$\sum_{t=1}^T \mathbf{x}_t^\top \ell_t \leq \sum_{t=1}^T \ell_t(i^*) + \varepsilon \sum_{t=1}^T \mathbf{x}_t^\top \ell_t^2 + \frac{\log N}{\varepsilon}$$

of experts
 $\leq T + \frac{\log N}{\varepsilon}$
 $\leq \sqrt{T \log N}$

Corollary: we can also compete with the best probability distribution!

Theorem 1.5. Let l_t^2 denote the N -dimensional vector of square losses, i.e., $l_t^2(i) = l_t(i)^2$, let $\varepsilon > 0$, and assume all losses to be non-negative. The Hedge algorithm satisfies for any expert $i^* \in [N]$:

$$\sum_{t=1}^T \mathbf{x}_t^\top l_t \leq \sum_{t=1}^T l_t(i^*) + \varepsilon \sum_{t=1}^T \mathbf{x}_t^\top l_t^2 + \frac{\log N}{\varepsilon}$$

- Why?

calc. $\rightarrow i^* = \text{Dan}$ $P(\text{Dan})$
 $\rightarrow i^* = \text{Mary}$ $P(\text{Mary}) \in \mathcal{P}$
 $\rightarrow i^* = \text{Rocher}$ $P(\text{Rocher})$
 $\rightarrow i^* = \text{Reffler}$ $P(\text{Reffler})$

$$\sum_{t=1}^T \mathbf{x}_t^\top l_t \leq \sum_{i=1}^N P_i^\top l_t + \underbrace{2\sqrt{T \log N}}$$

HW 4.5

How does MW applies to the problem of linear query release?

Online query release without privacy

1. True data $p = x/n$, initial synthetic data $\tilde{p}_1 = 1/|\mathcal{X}|$

2. Adversary selects an online sequence of queries

• If $|q^T \tilde{p}_t - q^T p| \geq \alpha$

1. Output $q^T p$

2. Set the loss vector to be $\ell_t := \text{sign}(q^T \tilde{p}_t - q^T p) \cdot q$

3. Update $\tilde{p}_{t+1} = \text{Normalize}(\tilde{p}_t \cdot \exp(-\eta \ell_t))$

4. Increment t, i.e., $t = t + 1$

• Else: output $q^T \tilde{p}_t$

The regret bound of MW implies that the number of iterations of the MW algorithm is small!

Theorem 1.5. Let l_t^2 denote the N -dimensional vector of square losses, i.e., $l_t^2(i) = l_t(i)^2$, let $\varepsilon > 0$, and assume all losses to be non-negative. The Hedge algorithm satisfies for any expert $i^* \in [N]$:

$$\sum_{t=1}^T \mathbf{x}_t^\top l_t \leq \sum_{t=1}^T \langle l_t, p \rangle + \varepsilon \sum_{t=1}^T \mathbf{x}_t^\top l_t^2 + \frac{\log N}{\varepsilon}$$

$$\sum_{t=1}^T p_t^\top l_t \leq \sum_{t=1}^T p_t^\top l_t + \sqrt{T \log |X|}$$

$$\sum_{t=1}^T (p_t - p)^\top l_t$$

$$\sum_{t=1}^T (p_t - p)^\top q \cdot \text{sign}(p_t^\top q - p^\top q)$$

$$\sum_{t=1}^T |(p_t - p)^\top q|$$

$$T \alpha \leq \sum_{t=1}^T \text{error}_t \leq 2 \sqrt{T \log |X|}$$

$$\sqrt{T} \leq \frac{2 \sqrt{\log |X|}}{\alpha}$$

Private MW for online query release using **NumericSparse**

Online query release **with differential privacy**

1. True data $p = x/n$, initial synthetic data $\tilde{p}_1 = 1/|\mathcal{X}|$
2. Adversary selects an online sequence of queries

• If $|q^T \tilde{p}_t - q^T p| \geq \alpha$

Use AboveThresh for this

1. Output $q^T p$

Use Laplace mechanism

2. Set the loss vector to be $\ell_t := \text{sign}(q^T \tilde{p}_t - q^T p) \cdot q$

3. Update $\tilde{p}_{t+1} = \text{Normalize}(\tilde{p}_t \cdot \exp(-\eta \ell_t))$

4. Increment t, i.e., $t = t + 1$

• Else: output $q^T \tilde{p}_t$

Private MW for online query release using NumericSparse

Online query release with differential privacy

1. True data $p = x/n$, initial synthetic data $\tilde{p}_1 = 1/|\mathcal{X}|$
2. Adversary selects an online sequence of queries

$$\hat{\alpha} = \alpha + \text{Lap}(2/(n\epsilon_0))$$

- If $|q^T \tilde{p}_t - q^T p| + \text{Lap}(4/(n\epsilon_0)) \geq \hat{\alpha}$

1. Privately release $y = q^T p + \text{Lap}(1/(n\epsilon_0))$
2. Set the loss vector to be $\ell_t := \text{sign}(q^T \tilde{p}_t - y) \cdot q$
3. Update $\tilde{p}_{t+1} = \text{Normalize}(\tilde{p}_t \cdot \exp(-\eta \ell_t))$
4. Increment t, i.e., $t = t + 1$. Break if $t > N$
5. Refresh threshold noise: $\hat{\alpha} = \alpha + \text{Lap}(2/(n\epsilon_0))$

- Else: output $q^T \tilde{p}_t$

Privacy analysis is straightforward.

- The algorithm runs ϵ_0 -DP AboveThresh + Laplace Mechanism for at most N times.
 - Total privacy loss bounded by $2N\epsilon_0$
 - We could choose $2N\epsilon_0 = \epsilon_{\text{budget}}$
- Note unique. How to choose N, ϵ_0 ?
 - We need to choose ϵ_0 s.t. the accuracy criteria is met.
 - We need to guess (and bound) the number of iterations the Hedge algorithms will need to run.
 - Choose one pair of N, ϵ_0 that works.

Utility analysis of the private MW Mechanism

1. Bound all Laplace random variables (how many are they?)

$2N + k$ Lap R.V. $\frac{4}{n\epsilon_0}$ w.p $1-\delta$, all of them $|Z| \leq \frac{4}{n\epsilon_0} \log \frac{2N + k}{\delta}$

$2N + k \leq 3k$

2. All that are not selected are getting accurate answers

Rule: $|q_i^T P_t - q_i^T P| + V_i < \alpha + \epsilon \Rightarrow \downarrow \Rightarrow |q_i^T P_t - q_i^T P| \leq \alpha + |\epsilon + V_i| \leq \alpha + \frac{\epsilon}{n\epsilon_0} \log \frac{3k}{\delta}$

3. All that are selected are also getting accurate answers

Rule: $|q_i^T P_t - q_i^T P| + V_i \geq \alpha + \epsilon \Rightarrow \uparrow \Rightarrow q_i^T P + w \Rightarrow \frac{w}{|w|} \leq \frac{4}{n\epsilon_0} \log \frac{3k}{\delta}$

4. From the regret bound of MW, the number of iterations is small

Regret = $\sum_t P_t^T q - P^T q = \sum_t (P_t - P)^T q \cdot \text{sign}(P_t^T q - (P^T q + w))$

condition on "T", $|q_i^T P_t - q_i^T P| \geq \alpha + \epsilon - V_i > \frac{\alpha}{2}$

$\frac{T\alpha}{2} \leq 2 \int \sqrt{T \log X}$

$T < \frac{16 \log X}{\alpha^2}$

$\text{sign}(P_t^T q - P^T q - w) = \text{sign}(P_t^T q - P^T q)$

Summarize the result into a theorem statement

- Choose these parameters

- $\epsilon_0 = \frac{16 \log \frac{3k}{\delta}}{n\alpha}$

- $N = \frac{16 \log |\mathcal{X}|}{\alpha^2}$

$$\underline{\epsilon_{total}} = 2\epsilon_0 N = \frac{512 \log \frac{3k}{\delta} \log |\mathcal{X}|}{n\alpha^3}$$

$$\frac{4 \log \frac{3k}{\delta}}{n\epsilon_0} \leq \frac{1}{4}\alpha$$

$$\epsilon_0 = \frac{16 \log \frac{3k}{\delta}}{n\alpha}$$

Theorem (Utility of Private MW): With probability at least $1 - \delta$, The private MW algorithm calibrated to achieve with ϵ -DP is able to answer any online sequence of $|\mathcal{Q}| = k$ linear queries and a max error of:

$$\alpha \leq \frac{1}{1.25} \left(\frac{512 \log \frac{3k}{\delta} \log |\mathcal{X}|}{n\epsilon} \right)^{\frac{1}{3}}$$

$$\frac{1}{\sqrt{n}}$$

log: ① $\frac{|\mathcal{Q}| \log |\mathcal{X}|}{n\epsilon}$
 ② $\frac{\sqrt{|\mathcal{X}|} \log \frac{3k}{\delta}}{n\epsilon}$

Remainder of today's lecture

- Introducing the problem of private selection
- Exponential mechanism
- The privacy analysis of exponential mechanism

Private selection

- A (large) set of items, and a utility function.

$$\mathcal{R} \qquad u : \mathbb{N}^{\mathcal{X}} \times \mathcal{R} \rightarrow \mathbb{R}$$

output
 $r^* = \underset{r \in \mathcal{R}}{\text{argmax}} U(x, r)$
data
item

- Example 1 (Most popular movie)

$\{ \text{Titanic}, \text{Rush Hour}, \text{Angels in America} \} = \mathcal{R}$
 $U(x, r) = \# \text{ of users who "liked" } r$

- Example 2 (Learning a classifier)

$\mathcal{R} := \{ \text{Decision tree } l, \text{ Linear Classifier } \theta_1, \text{ LC } \theta_2, \dots \}$
 $U(x, r) = - \sum_{i=1}^n \text{err}_i(r, x_i)$

- Example 3 (Auction)

$\mathcal{R} = \{ \text{price to sell an item} \} \rightarrow 0.5, 1, 1.25, \dots, (\infty)$
 $U(x, r) = r \cdot \# \text{ of people who willing to buy}$

Exponential mechanism

- Global sensitivity of the utility function

$$\Delta u \equiv \max_{r \in \mathcal{R}} \max_{x, y: \|x-y\|_1 \leq 1} |u(x, r) - u(y, r)|.$$

- The exponential mechanism samples an output from a “Gibbs distribution”:

$$\mathcal{M}(x) \sim p(r|x) \propto \exp\left(\frac{\varepsilon u(x, r)}{2\Delta u}\right)$$

Privacy Analysis of Exponential Mechanism

$$\begin{aligned}
 \frac{P_x(r)}{P_{x'}(r)} &= \frac{e^{\frac{\epsilon u(x,r)}{2\Delta}}}{e^{\frac{\epsilon u(x',r)}{2\Delta}}} \cdot \frac{\sum_{r \in \mathcal{R}} e^{\frac{\epsilon u(x,r)}{2\Delta}}}{\sum_{r \in \mathcal{R}} e^{\frac{\epsilon u(x',r)}{2\Delta}}} \\
 &= e^{\frac{\epsilon(u(x,r) - u(x',r))}{2\Delta}} \cdot \frac{\sum_{r \in \mathcal{R}} e^{\frac{\epsilon(u(x',r) - u(x,r) + u(x,r))}{2\Delta}}}{\sum_{r \in \mathcal{R}} e^{\frac{\epsilon u(x,r)}{2\Delta}}} \\
 &\leq e^{\frac{\epsilon}{2\Delta}} \cdot \frac{\sum_{r \in \mathcal{R}} e^{\frac{\epsilon u(x,r)}{2\Delta}}}{\sum_{r \in \mathcal{R}} e^{\frac{\epsilon u(x,r)}{2\Delta}}} \\
 &\leq e^{\frac{\epsilon}{2\Delta}} \cdot 1 \\
 &= e^{\frac{\epsilon}{2\Delta}}
 \end{aligned}$$

Randomized response and Laplace mechanism are instances of exponential mechanisms!

Next lecture
