

CS 267: Automated Verification

Lecture 9: LTL Buchi Automata Translation

Instructor: Tevfik Bultan

LTL

- We are going to discuss LTL to Buchi automata translation
- First let's recall LTL semantics
- I will also add a new operator called R (release) to make the translation to Buchi automata easier

LTL Semantics

Given an execution path x and LTL properties p and q

$x \models p$ iff $L(x_0, p) = \text{True}$, where $p \in AP$

$x \models \neg p$ iff not $x \models p$

$x \models p \wedge q$ iff $x \models p$ and $x \models q$

$x \models p \vee q$ iff $x \models p$ or $x \models q$

$x \models X p$ iff $x^1 \models p$

$x \models G p$ iff for all $i \geq 0$, $x^i \models p$

$x \models F p$ iff there exists an $i \geq 0$ such that $x^i \models p$

$x \models p U q$ iff there exists an $i \geq 0$ such that $x^i \models q$ and
for all $0 \leq j < i$, $x^j \models p$

$x \models p R q$ iff for all $j \geq 0$, if for all $0 \leq i < j$, $x^i \not\models p$
then $x^j \models q$

LTL Equivalences

- Given an LTL formula convert it to positive normal form:
 - Negations are only applied to atomic propositions (there is no negation outside of a temporal operator)
- Use the following equivalences to translate the LTL formulas to positive normal form:

$$\neg(p \text{ U } q) \equiv \neg p \text{ R } \neg q$$

$$\neg(p \text{ R } q) \equiv \neg p \text{ U } \neg q$$

$$\neg(\text{X } p) \equiv \text{X } \neg p$$

$$\neg(p \text{ R } q) \equiv \neg p \text{ U } \neg q$$

$$\text{F } p \equiv \text{true } \text{ U } p$$

$$\text{G } p \equiv \text{false } \text{ R } p$$

LTL Buchi Automata Translation

[Gerth, Peled, Vardi, Wolper 95]

- *Each state of the automata will store a set of properties that should be satisfied on paths starting at that state*
 - These properties will be stored in lists called *Old* and *New* where *Old* means already processed and *New* means still needs to be processed
- *Each state will also store a set of properties which should be satisfied on paths starting at the next states of that state*
 - These properties will be stored in the list *Next*
- The incoming transitions for a state will be stored in the list *Incoming*

LTL Buchi Automata Translation

- We will start with a node which has the input LTL property in its New list
- We will process the formulas in the New list of each node one by one
 - When we have $f \text{ U } g$ in the New list we will use
$$f \text{ U } g \equiv g \vee (f \wedge X (f \text{ U } g))$$
 - When we have $f \text{ R } g$ in the New list we will use
$$f \text{ R } g \equiv g \wedge (f \vee X (f \text{ R } g))$$

LTL Buchi Automata Translation

- When we process a formula from a node we will either replace the node with a new node or we will replace it with two new nodes (i.e., we will split it to two nodes)

– When a node q is replaced by a node q' we will have

$$(\text{Old}(q) \wedge \text{New}(q) \wedge X \text{Next}(q)) \Leftrightarrow (\text{Old}(q') \wedge \text{New}(q') \wedge X \text{Next}(q'))$$

– When a node q is split into two nodes q_1 and q_2 we will have

$$\begin{aligned} & (\text{Old}(q) \wedge \text{New}(q) \wedge X \text{Next}(q)) \\ \Leftrightarrow & ((\text{Old}(q_1) \wedge \text{New}(q_1) \wedge X \text{Next}(q_1)) \\ & \vee (\text{Old}(q_2) \wedge \text{New}(q_2) \wedge X \text{Next}(q_2))) \end{aligned}$$

Translate(f) { expand([Incoming:={init}, Old:= \emptyset , New:={f}, Next:= \emptyset], \emptyset) }

Expand(q, NodeList) {

If New(q) is empty

then

if there exists a node r in NodeList s.t. Old(r) = Old(q) and Next(r) = Next(q)

then Incoming(r) := Incoming(q) \cup Incoming(r);

return(NodeList);

else create a new node q' s.t. Incoming(q')=q, Old(q')= \emptyset ,
New(q')=Next(q), Next:= \emptyset ;

return expand(q' , Nodelist \cup {q});

else // New(q) is not empty

pick a formula f from New(q) and remove it from New(q);

if f is already in Old(q) then return expand(q, Nodelist);

else if (f \in AP or Neg(f) \in AP or f is a boolean constant)

then if (f \equiv false or Neg(f) \in Old(q)) then return(Nodelist);

else create a node q' s.t.

Incoming(q')=Incoming(q),

Old(q')=Old(q) \cup {f},

New(q')=New(q) - {f},

Next(q')=Next(q);

return expand(q' , Nodelist);

else if ($f \equiv h \vee k$)

create two nodes q_1 and q_2 s.t

$\text{Incoming}(q_1) = \text{Incoming}(q_2) = \text{Incoming}(q)$,

$\text{Old}(q_1) = \text{Old}(q_2) = \text{Old}(q) \cup \{h \vee k\}$,

$\text{New}(q_1) = (\text{New}(q) - \{h \vee k\}) \cup \{h\}$,

$\text{New}(q_2) = (\text{New}(q) - \{h \vee k\}) \cup \{k\}$,

$\text{Next}(q_1) = \text{Next}(q_2) = \text{Next}(q)$;

return $\text{expand}(q_2, \text{expand}(q_1, \text{Nodelist}))$;

else if ($f \equiv h \wedge k$)

create a node q' s.t.

$\text{Incoming}(q') = \text{Incoming}(q)$,

$\text{Old}(q') = \text{Old}(q) \cup \{h \wedge k\}$,

$\text{New}(q') = (\text{New}(q) - \{h \wedge k\}) \cup \{h\} \cup \{k\}$,

$\text{Next}(q') = \text{Next}(q)$;

return $\text{expand}(q', \text{Nodelist})$;

else if ($f \equiv X h$)

create a node q' s.t.

$\text{Incoming}(q') = \text{Incoming}(q)$,

$\text{Old}(q') = \text{Old}(q) \cup \{X h\}$,

$\text{New}(q') = \text{New}(q) - \{X h\}$,

$\text{Next}(q') = \text{Next}(q) \cup \{h\}$;

return $\text{expand}(q', \text{Nodelist})$;

else if ($f \equiv h \cup k$) // using the equivalence $h \cup k \equiv k \vee (h \wedge X (h \cup k))$

create two nodes q_1 and q_2 s.t.

$\text{Incoming}(q_1) = \text{Incoming}(q_2) = \text{Incoming}(q)$,

$\text{Old}(q_1) = \text{Old}(q_2) = \text{Old}(q) \cup \{h \cup k\}$,

$\text{New}(q_1) = \text{New}(q) \cup \{h\}$,

$\text{New}(q_2) = \text{New}(q) \cup \{k\}$,

$\text{Next}(q_1) = \text{Next}(q) \cup \{h \cup k\}$,

$\text{Next}(q_2) = \text{Next}(q)$;

return $\text{expand}(q_2, \text{expand}(q_1, \text{Nodelist}))$;

else if ($f \equiv h \text{ R } k$) // using the equivalence $h \text{ R } k \equiv k \wedge (h \vee X (h \text{ R } k))$

// $\equiv (k \wedge h) \vee (k \wedge X (h \text{ R } k))$

create two nodes q_1 and q_2 s.t.

$\text{Incoming}(q_1) = \text{Incoming}(q_2) = \text{Incoming}(q)$,

$\text{Old}(q_1) = \text{Old}(q_2) = \text{Old}(q) \cup \{h \text{ R } k\}$,

$\text{New}(q_1) = \text{New}(q) \cup \{h, k\}$,

$\text{New}(q_2) = \text{New}(q) \cup \{k\}$,

$\text{Next}(q_1) = \text{Next}(q)$,

$\text{Next}(q_2) = \text{Next}(q) \cup \{h \text{ R } k\}$;

return $\text{expand}(q_2, \text{expand}(q_1, \text{Nodelist}))$;

Completing the Automaton

The resulting Buchi automaton $A = (\Sigma, Q, \Delta, Q_0, F)$

$$\Sigma = 2^{AP}$$

$$Q = \text{Nodelist} \cup \{\text{init}\}$$

$$Q_0 = \{\text{init}\}$$

Δ is defined as follows:

$(q, d, q') \in \Delta$ iff $q \in \text{Incoming}(q')$ and
 d satisfies the conjunction of negated and
unnegated propositions in $\text{Old}(q')$

$$F \subseteq 2^Q \text{ i.e., } F = \{F_1, F_2, \dots, F_k\}$$

The acceptance set F contains a set of accepting states $F_i \in F$
for each subformula of the form $h \cup k$ where F_i contains all
the states q s.t. either $k \in \text{Old}(q)$ or $h \cup k \notin \text{Old}(q)$

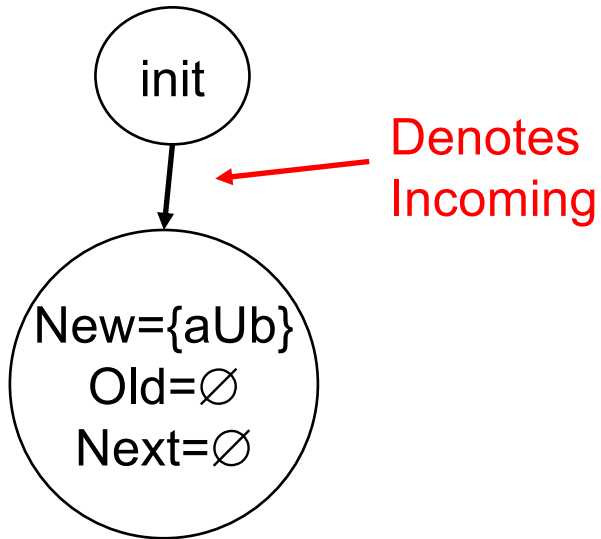

If there are no subformulas of the form $h \cup k$ then $F = \{Q\}$

Resulting Automaton

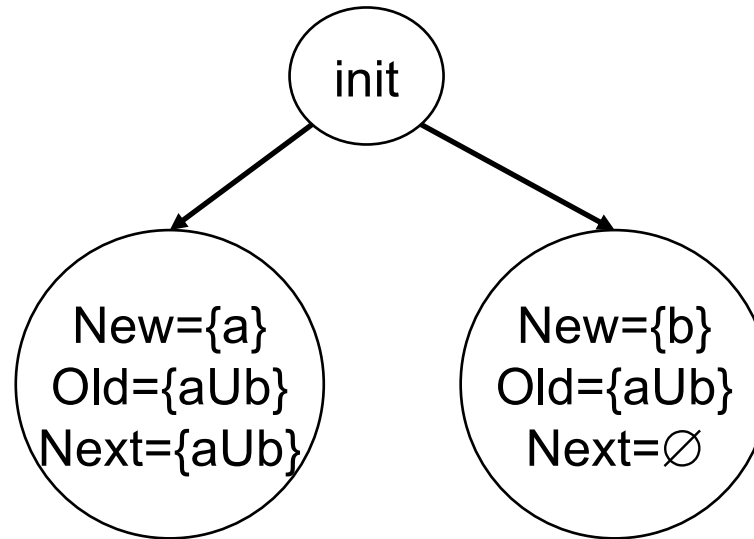

- The size of the resulting automaton can be exponential in the size of the input formula
- The resulting automaton is a generalized Buchi automaton
 - we can translate it to a standard Buchi automaton as we discussed earlier

Example Formula: $a \cup b$ where $AP = \{a, b\}$

Step 1: Nodelist= \emptyset

Step 2: Nodelist= \emptyset

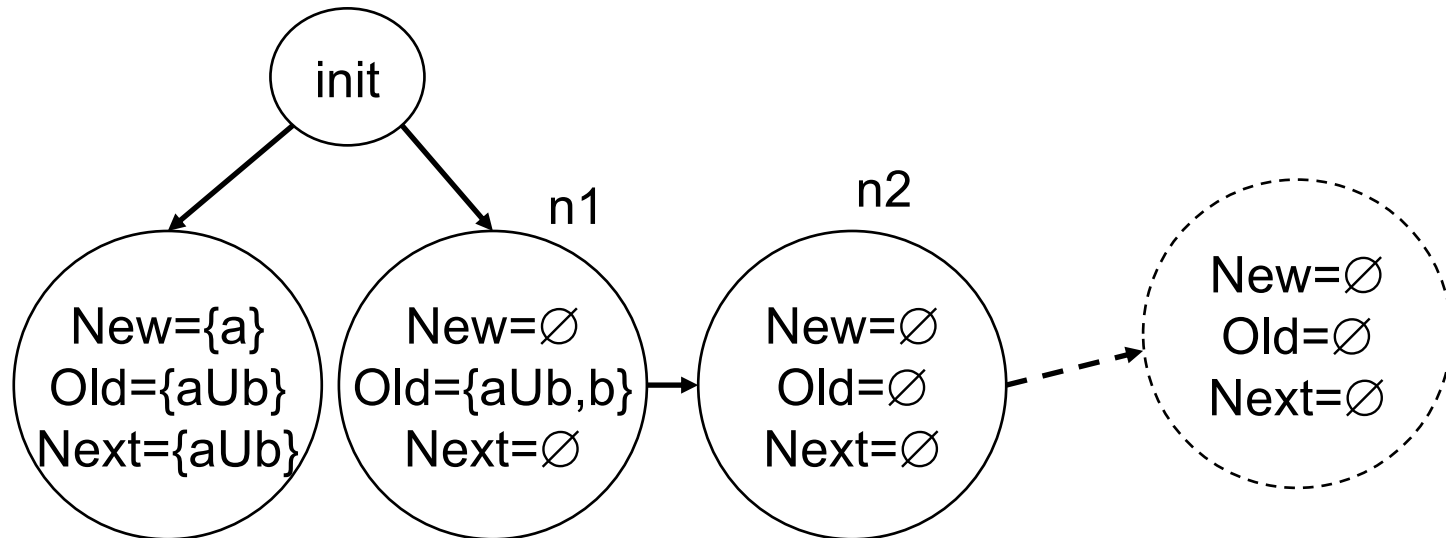

Step 3: Nodelist={n1}

Example (cont' d)

Step 4: Nodelist={n1,n2}

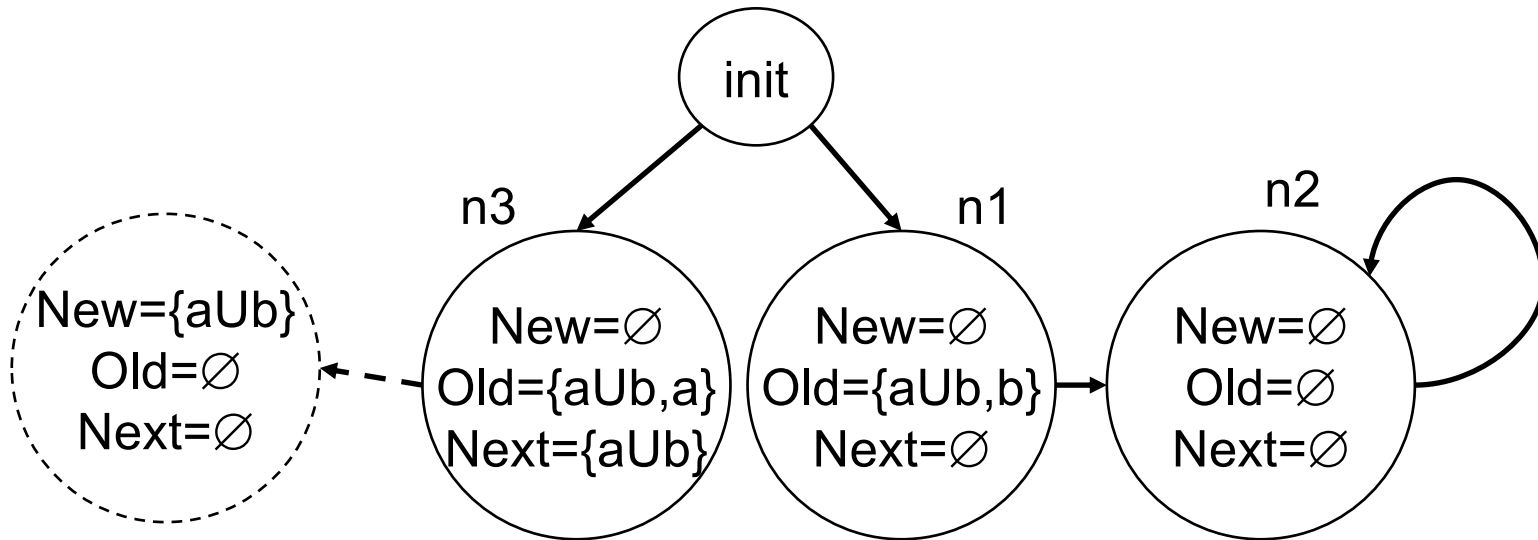

Step 5: Nodelist={n1,n2}

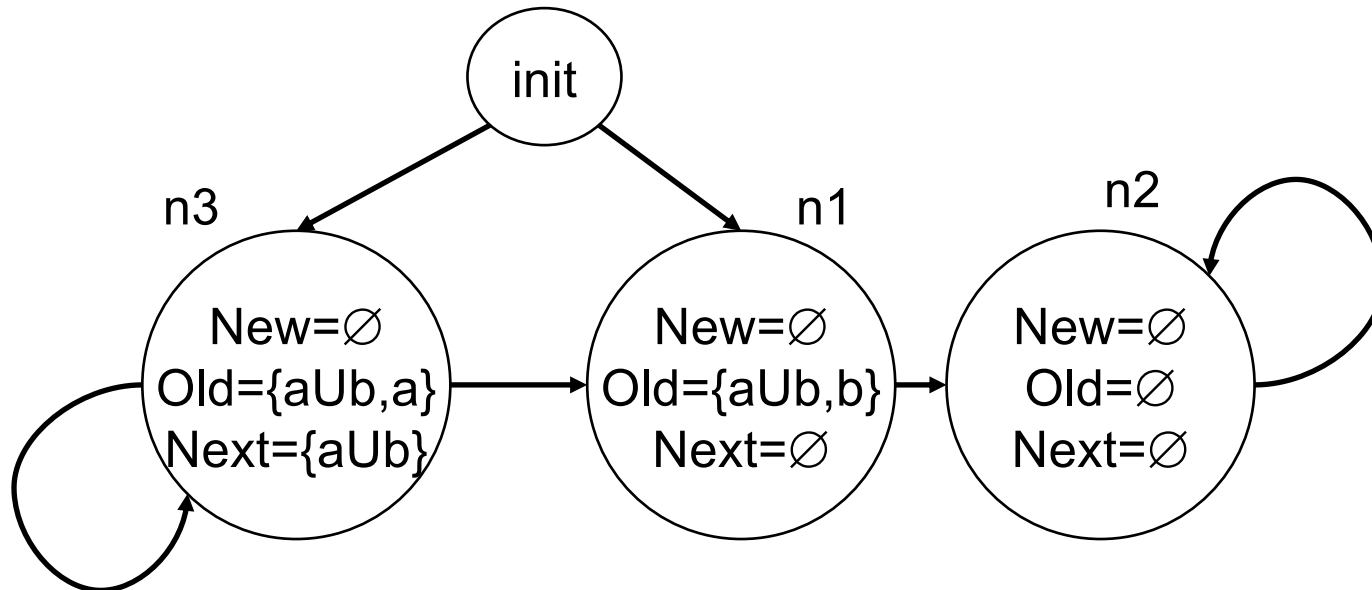

Example (Cont' d)

Step 5: Nodelist={n1,n2,n3}

Step 6: Nodelist={n1,n2,n3}

Example (Cont' d)

Final Step: Complete the Automaton

$$\Sigma = 2^{AP} = \{ \emptyset, \{a\}, \{b\}, \{a, b\} \}$$

$$F = \{ \{n1, n2\} \}$$

$$Q = \{init, n1, n2, n3\}$$

$$Q_0 = \{init\}$$
