Abstract

In the Split Vertex Deletion (SVD) problem, the input is an \(n\)-vertex undirected graph \(G\) and
a weight function \(w : V(G) \rightarrow \mathbb{N}\), and the objective is to find a minimum weight subset \(S\) of vertices
such that \(G - S\) is a split graph (i.e., there is bipartition of \(V(G - S) = C \uplus I\) such that \(C\) is a
clique and \(I\) is an independent set in \(G - S\)). This problem is a special case of 5-Hitting Set and
consequently, there is a simple factor 5-approximation algorithm for this. On the negative side, it is
easy to show that the problem does not admit a polynomial time \((2 - \delta)\)-approximation algorithm,
for any fixed \(\delta > 0\), unless the Unique Game Conjecture fails.

We start by giving a simple quasipolynomial time \(n^{O(\log n)}\) factor 2-approximation algorithm
for SVD using the notion of clique-independent set separating collection. Thus, on the one hand SVD
admits a factor 2-approximation in quasipolynomial time, and on the other hand this approximation
factor cannot be improved assuming UGC. It naturally leads to the following question: Can SVD be
2-approximated in polynomial time? In this work we almost close this gap and prove that for any \(\varepsilon > 0\), there is a \(n^{O(\log \frac{1}{\varepsilon})}\)-time \((1 + \varepsilon)\)-approximation algorithm.

1 Introduction

The Hitting Set problem encompasses a large number of well studied problems in Computer Science. Here, the input is a family \( \mathcal{F} \) of sets over an \( n \)-element universe \( U \) and a weight function \( w : U \to \mathbb{N} \), and the objective is to compute a hitting set of minimum weight. A hitting set is a subset \( S \subseteq U \) such that for any \( F \in \mathcal{F} \), \( F \cap U \neq \emptyset \) and the weight of \( S \) is \( w(S) = \sum_{u \in S} w(u) \). Consequently, this problem is very hard to approximate: it can not be approximated within a factor \( 2^{\log^{1-\epsilon} n} \) in polynomial time, for any constant \( \epsilon < 1/2 \), unless SAT can be decided in slightly subexponential time, where \( \delta_c(n) = 1/(\log \log n) \) [12].

A restricted version of this problem, is the \( d \)-Hitting Set problem, where \( d \in \mathbb{N} \) and the cardinality of every set in \( \mathcal{F} \) is at most \( d \). This problem also generalizes a number of well studied problems, and it admits a simple factor \( d \)-approximation algorithm: Solve the natural LP relaxation and select all elements whose corresponding variable in the LP is set to at least \( 1/d \). Unfortunately, this simple algorithm is likely to be the best possible. That is, assuming Unique Game Conjecture (UGC), there is no \( c \)-factor approximation algorithm for \( d \)-Hitting Set, for any \( c < d \) in the general case [8].

A number of vertex deletion problems on graphs are can be considered as special cases of \( d \)-Hitting Set, and it is of great interest to devise factor-\( \alpha \) approximation algorithm for them where \( \alpha < d \), or rule out any such algorithm. For example, in the Vertex Cover problem, the input is a graph \( G \) and a weight function \( w : V(G) \to \mathbb{N} \), and the objective is to find a subset of vertices of minimum weight that hits all edges in \( G \). This is same as 2-Hitting Set, and assuming the Unique Games Conjecture we cannot do better. However, there are other examples of vertex deletion problems on graphs, that are special cases of \( d \)-Hitting Set, for which we can indeed do better. Consider the Cluster Vertex Deletion problem, where the input is a graph \( G \) and a weight function \( w : V(G) \to \mathbb{N} \), and the objective is to find a minimum weight subset \( S \) of vertices such that \( S \) is a cluster graph. Equivalently, \( S \) hits all induced paths of length 3 in \( G \). Hence, it is a special case of 3-Hitting Set and admits a simple 3-approximation algorithm. You et al. [14] showed that the unweighted version of Cluster Vertex Deletion admits a 5/2 approximation algorithm. Recently, this was improved to factor 9/4 by Fiorini et al. [6]. The problem also admits an approximation-preserving reduction from Vertex Cover and hence there is a lower bound of 2 on the approximation-factor assuming UGC [6]. Fiorini et al. [6] have conjectured that Cluster Vertex Deletion admits a 2-approximation algorithm. Another example which is the Tournament Feedback Vertex Set (TFVS) problem, which is equivalent to hitting all directed triangles in a digraph. It is very well studied in the realm of approximation algorithms [4, 1, 11, 10], and very recently a 2-approximation algorithm was designed by Lokshavanov et al. [10], matching the lower-bound under UGC [13].

Similarly, a number of such “implicit” \( d \)-Hitting Set problems are studied in Computer Science, and it is of great interest to settle their approximation complexity.

In this work we study another implicit \( d \)-Hitting Set problem called Split Vertex Deletion (SVD) (defined below). A subset \( S \) of vertices in a graph \( G \) is a split vertex deletion set if \( G - S \) is a split graph (i.e., there is bipartition of \( V(G - S) = C \uplus I \) such that \( C \) is a clique and \( I \) is an independent set in \( G - S \)).

**Split Vertex Deletion (SVD)**

**Input:** An undirected graph \( G \) and a weight function \( w : V(G) \to \mathbb{N} \).

**Output:** A split vertex deletion set \( S \subseteq V(G) \) of \( G \) of the smallest weight (an optimum split vertex deletion set of \( G \)).

A graph \( G \) is a split graph if and only if it does not contain \( C_4, C_5 \) and \( 2K_2 \) as induced
subgraphs in $G$. This implies that SVD is special case of 5-Hitting Set and hence it admits
a simple 5-approximation algorithm. Furthermore, it is interesting to note that we can obtain
a 2-approximation algorithm for SVD in time $n^{O(\log n)}$ using the notion of clique-independent
set separating collection. For a graph $G$, a clique-independent set separating collection is a
family $\mathcal{C}$ of vertex subsets of $V(G)$ such that for a clique $C$ and an independent set $I$ in $G$
such that $C \cap I = \emptyset$, there is subset $X$ in the collection $\mathcal{C}$ such that $C \subseteq X$ and $I \subseteq V(G) \setminus X$.
Thus, if there is a “small” clique-independent set separating collection, then we can enumerate
such a collection $\mathcal{C}$ and solve Vertex Cover of $\overline{G}[X]$ and $G - X$ for each $X \in \mathcal{C}$. Notice
that for any $X \in \mathcal{C}$, the union of the two solutions of Vertex Cover instances on $\overline{G}[X]$ and
$G - X$ is a solution to SVD. Moreover, the best $c$-approximation solutions over all choices
of $X$, is a $c$-approximate solution of SVD. It is known that for any $n$-vertex graph, there is
clique-independent set separating collection of size $n^{O(\log n)}$ and this can be enumerated in
time linear in the size of the collection [5]. This along with a 2-approximation algorithm of
Vertex Cover leads to a $n^{O(\log n)}$-time 2-approximation algorithm for SVD. There is also a
simple approximation preserving reduction from Vertex Cover to SVD, which shows that
we cannot improve upon factor 2-approximation algorithm, unless UGC fails. The reduction
is as follows: Given an instance $(G, w)$ of Vertex Cover, we add a large complete graph $H$
of size $2|V(G)|$ into $G$ with weight of each vertex in $H$ to be $\max\{w(u) : u \in V(G)\}$. One
can easily verify that this is an approximation preserving reduction.

Thus, on the one hand SVD admits a 2-approximation in quasipolynomial $(n^{O(\log n)})$
time, and on the other hand this approximation factor cannot be improved assuming UGC.
It naturally leads to the following question: Can SVD be 2-approximated in polynomial time?
This is precisely the question we address in this paper, and obtain the following result.

**Theorem 1.** There exists a randomized algorithm that given a graph $G$, a weight function
$w$ on $V(G)$ and $\varepsilon > 0$, runs in time $O(n^{9(\varepsilon)})$ and outputs $S \subseteq V(G)$ such that
$G - S$ is a split graph and $w(S) \leq 2(1 + \varepsilon)w(OPT)$ with probability at least $1/2$, where
$OPT$ is a minimum weight split vertex deletion set of $G$. Here, $g(\varepsilon) = 6 + 8(80(1 + \frac{12}{\varepsilon})) \cdot \log(\frac{20}{\varepsilon}) / \log(4/3)$.

**Overview of Theorem 1.** At a very high level the algorithm described in Theorem 1 is
inspired from the algorithm developed for factor 2-approximation algorithm for TFVS [10].
In TFVS knowing just one vertex is sufficient to completely split the instance into two
independent sub-instances and thus leading to a natural divide and conquer scheme. However,
in our case (SVD) the instances don’t become truly independent before every vertex is
classified as either potential clique or potential independent set vertex. To classify all the
vertices requires several new ideas and insights in the problem. This classification could be
be vaguely viewed as a polynomial time algorithm that quickly navigates through sets in
clique-independent set separating collection, $\mathcal{C}$, and almost reaches a correct partition.

Our algorithm in fact finds a $(2 + \varepsilon)$-factor approximate solution for a more general
annotated variant of the problem, where the solution must obey certain additional constraints.

**Annotated Split Vertex Deletion (A-SVD)**

**Input:** An undirected graph $G$, a weight function $w : V(G) \to \mathbb{N}$, and a partition of
$V(G)$ into three parts $V(G) = C \cup I \cup U$, where at most two of these parts may be empty.

**Output:** A set $S^* \subseteq V(G)$ of $G$ of the smallest weight such that $G - S^*$ is a split graph
with a split partition $(C^*, I^*)$ where $C^* \subseteq (C \cup U)$ and $I^* \subseteq (I \cup U)$ hold.

A feasible solution to an instance $(G, w, (C, I, U))$ of Annotated Split Vertex Deletion
is a split vertex deletion set $S$ of $G$ such that the split graph $G - S$ has a split partition
$(C^*, I^*)$ where no vertex in the specified set $I$ goes to the split part $C^*$ and no vertex in the
specified set $C$ goes to the independent part $I^*$. Thus, each vertex in the set $I$ is either
deleted as part of $S$ or ends up in the independent set $I'$ in graph $G - S$, and each vertex in $C$ is either deleted or ends up in the clique $C'$ in $G - S$. There are no restrictions on where the vertices in the “unconstrained” set $U$ may go. We call a feasible solution of A-SVD an annotated split vertex deletion set of the instance $(G, w, (C, I, U))$: the A-SVD problem asks for an optimum annotated split vertex deletion set of the input instance.

First we show that we can, in polynomial time, find $2$-factor approximate solutions to A-SVD instances which are of the form $(G, w, (C, I, U))$ (Lemma 12). Let $(G, w, (C, I, U))$ be an instance of A-SVD, let $OPT$ be an (unknown) optimum solution to $(G, w, (C, I, U))$, let $(C', I', U')$ be a split partition of $G - OPT$, and let $C_U^* = (C' \cap U)$, $I_U^* = (I' \cap U)$. We show that if $w(C_U^* \setminus \{c^*\}) \leq \frac{\varepsilon w(OPT)}{2}$ holds for some $c^* \in C_U^*$ or $w(I_U^* \setminus \{i^*\}) \leq \frac{\varepsilon w(OPT)}{2}$ holds for some $i^* \in I_U^*$ then we can, in polynomial time, find a $(2 + \varepsilon)$-factor approximate solution to $(G, w, (C, I, U))$ (Lemma 16, Lemma 18). These constitute the base cases of our algorithm. It is not difficult to see that moving a vertex $x \in C_U^*$ to the set $C$ and moving a vertex $y \in I_U^*$ to the set $I$ are approximation-preserving transformations. At a high level, our algorithm starts with an arbitrary instance $(G, w, (C, I, U))$ of A-SVD, correctly identifies—with a constant probability of success—a good fraction of vertices which belong to the sets $C_U^*$ or $I_U^*$, and moves these vertices to the sets $C$ or $I$, respectively. It then recurses on the resulting instance, till it reaches one of the base cases described above.

We now briefly and informally outline how our algorithm identifies vertices as belonging to $C_U^*$ or $I_U^*$. Consider the bipartite subgraph $H$ of $G$ induced by the pair $(C_U^*, I_U^*)$. Define the weight of an edge to be the product of the weights of its two end-points, and suppose the total weight of edges in $H$ is at least half the maximum possible weight. Then each of a constant fraction (by weight) of the vertices in $I_U^*$ has a constant fraction (by weight) of $C_U^*$ in its neighbourhood (Lemma 4). If we can identify one of these special vertices of $I_U^*$ then we can safely move all its neighbours in $U$ to the set $C$ while reducing the weight of $C_U^*$ by a constant fraction. The catch, of course, is that we have no idea what the set $I_U^*$ is.

To get around this, we find an approximate solution $X$ of the Split Vertex Deletion instance defined by the induced subgraph $G[U]$. Let $(C_X, I_X)$ be a split partition of $G - U$. We show that we can, in polynomial time and with constant probability, sample a vertex from the set $X \cup (I_X \setminus C_X^*)$ (Lemma 26). We further show that the weight of $X \cup (I_X \setminus C_X^*)$ is at most a constant multiple of the weight of $I_U^*$ (Lemma 22). So if $I_U^* \subseteq (X \cup (I_X \setminus C_X^*))$ holds then we can, with good probability, sample a vertex from the set $I_U^*$. The hard part is when this condition does not hold. We show using a series of lemmas that we can, even in this case, sample a vertex from one of the two sets $C_U^*, I_U^*$ with constant probability. A symmetric analysis applies when the total weight of non-edges across $(C_U^*, I_U^*)$ is at least half the maximum possible weight.

**Organization of the rest of the paper.** In section 2 we collect together various preliminary results. We describe our algorithm in section 3; in subsection 3.1 we describe how to deal with instances whose vertex weights are bounded by some constant-degree polynomial in the number of vertices, and in subsection 3.2 we show how to extend this to instances with arbitrary weights. We conclude in section 4.

## 2 Preliminaries

We use $\uplus$ to denote the disjoint union of sets. Moreover, when we write $X \uplus Y$ we implicitly assert that the sets $X$ and $Y$ are disjoint. We use $V(G)$ (respectively, $E(G)$) to denote the vertex set (respectively, the edge set) of graph $G$. For a subset $S \subseteq V(G)$ of vertices of $G$ we use $G[S]$ to denote the subgraph of $G$ induced by $S$ and $G - S$ to denote the subgraph of
For a graph \( G \) and any two disjoint vertex subsets \( X, Y \subseteq V(G) : X \cap Y = \emptyset \) the bipartite subgraph of \( G \) induced by the pair \((X,Y)\) has vertex set \( X \cup Y \) and edge set \( \{ xy \mid x \in X, y \in Y, xy \in E(G) \} \). Note that the bipartite subgraph of \( G \) induced by the pair \((X,Y)\) is not necessarily identical to the subgraph \( G[X \cup Y] \) induced by the subset \( X \cup Y \), and is defined even if the induced subgraph \( G[X \cup Y] \) is not bipartite. For a bipartite graph \( H \) with vertex bipartition \( V(H) = V_1 \uplus V_2 \) we define \( E(H) = \{ v_1v_2 \mid v_1 \in V_1, v_2 \in V_2, v_1v_2 \notin E \} \) to be the set of all non-edges of \( H \) with one end in \( V_1 \) and the other end in \( V_2 \). Further, for a weight function \( w : V(H) \to \mathbb{N} \) defined on the vertex set of a bipartite graph \( H \) we define the weight of its edge set to be \( w(E(H)) = \sum_{v_1v_2 \in E(H)} (w(v_1) \cdot w(v_2)) \) and the weight of its set of non-edges to be \( w(E(H)) = \sum_{v_1v_2 \in E(H)} (w(v_1) \cdot w(v_2)) \).

**Definition 3.** Let \( G \) be an undirected graph and \( w : V(G) \to \mathbb{N} \) a weight function. Let \( X, Y \) be two disjoint vertex subsets of \( G \) and let \( H \) be the bipartite subgraph of \( G \) induced by the pair \((X,Y)\). Let \( w(E(H)) \) and \( w(E(H)) \) be defined as above. We say that \((X,Y)\) is a heavy pair if \( w(E(H)) \geq \frac{w(X) \cdot w(Y)}{2} \) holds, and is a light pair if \( w(E(H)) \geq \frac{w(X) \cdot w(Y)}{2} \) holds.

**Lemma 4.** Let \( H = (V,E) \) be a bipartite graph, let \( V = V_1 \uplus V_2 \) be a bipartition of \( H \), and let \( w : V(H) \to \mathbb{N} \) be a weight function. Then \((V_1,V_2)\) is either a heavy pair or a light pair. Moreover,

1. Suppose \((V_1,V_2)\) is a heavy pair, and let \( X = \{ x \in V_1 \mid w(N(x)) \geq \frac{w(V_2)}{4} \} \) be the set of all vertices \( x \) in the set \( V_1 \) such that the total weight of the neighbourhood of \( x \) in the set \( V_2 \) is at least one-fourth the total weight of the set \( V_2 \). Then \( w(X) > \frac{w(V_1)}{4} \).

2. Suppose \((V_1,V_2)\) is a light pair, and let \( Y = \{ y \in V_1 \mid w(V_1 \setminus N(y)) \geq \frac{w(V_2)}{4} \} \) be the set of all vertices \( y \) in the set \( V_1 \) such that the total weight of the non-neighbours of \( y \) in the set \( V_2 \) is at least one-fourth the total weight of the set \( V_2 \). Then \( w(Y) > \frac{w(V_1)}{4} \).

**Proof.** Observe that (i) every pair of vertices \((v_1,v_2)\) in the set \( V_1 \times V_2 \) is either an edge or a non-edge (and not both) in the bipartite graph \( H \), and (ii) every edge or non-edge with one end in the set \( V_1 \) and the other end in the set \( V_2 \) is an element of \( V_1 \times V_2 \). As a consequence
we get that
\[
\begin{align*}
w(E(H)) + w(\overline{E(H)}) &= \sum_{v_1, v_2 \in E(H)} (w(v_1) \cdot w(v_2)) + \sum_{v_1, v_2 \in \overline{E(H)}} (w(v_1) \cdot w(v_2)) \\
&= \sum_{(v_1, v_2) \in V_1 \times V_2} (w(v_1) \cdot w(v_2)) \\
&= \left( \sum_{v_1 \in V_1} w(v_1) \right) \cdot \left( \sum_{v_2 \in V_2} w(v_2) \right) \\
&= w(V_1) \cdot w(V_2).
\end{align*}
\]
It follows that the two terms \( \{w(E(H)), w(\overline{E(H)})\} \) cannot simultaneously be smaller than one half of \( w(V_1) \cdot w(V_2) \). Thus at least one of \( \{w(E(H)) \geq \frac{w(V_1) \cdot w(V_2)}{2}, w(\overline{E(H)}) \geq \frac{w(V_1) \cdot w(V_2)}{2}\} \) must hold.

We prove each of the two cases in turn.

1. By assumption the inequality \( w(N(v_1)) = \sum_{v_1, v_2 \in E(H)} w(v_2) < w(V_2) \) holds for each vertex \( v_1 \in (V_1 \setminus X) \). If possible, let it be the case that \( w(X) \leq \frac{w(V_1)}{4} \) holds. Then
\[
w(E(H)) = \sum_{v_1, v_2 \in E(H)} (w(v_1) \cdot w(v_2)) = \sum_{v_1 \in V_1} (w(v_1) \cdot \sum_{v_2 \in E(H)} w(v_2)) \\
= \sum_{v_1 \in X} (w(v_1) \cdot \sum_{v_2 \in E(H)} w(v_2)) + \sum_{v_1 \in (V_1 \setminus X)} (w(v_1) \cdot \sum_{v_2 \in E(H)} w(v_2)) \\
< \sum_{v_1 \in X} (w(v_1) \cdot w(V_2)) + \sum_{v_1 \in (V_1 \setminus X)} (w(v_1) \cdot \frac{w(V_2)}{4}) \\
= w(X) \cdot w(V_2) + w(V_1 \setminus X) \cdot \frac{w(V_2)}{4} \\
\leq \frac{w(V_1)}{4} \cdot w(V_2) + w(V_1) \cdot \frac{w(V_2)}{4} = \frac{w(V_1) \cdot w(V_2)}{4},
\]
a contradiction.

2. By assumption the inequality \( w(V_2 \setminus N(v_1)) = \sum_{v_1, v_2 \in \overline{E(H)}} (w(v_2)) < \frac{w(V_2)}{4} \) holds for each vertex \( v_1 \in (V_1 \setminus Y) \). If possible, let it be the case that \( w(Y) \leq \frac{w(V_1)}{4} \) holds. Then
\[
w(\overline{E(H)}) = \sum_{v_1, v_2 \in \overline{E(H)}} (w(v_1) \cdot w(v_2)) = \sum_{v_1 \in V_1} (w(v_1) \cdot \sum_{v_2 \in \overline{E(H)}} w(v_2)) \\
= \sum_{v_1 \in Y} (w(v_1) \cdot \sum_{v_2 \in \overline{E(H)}} w(v_2)) + \sum_{v_1 \in (V_1 \setminus Y)} (w(v_1) \cdot \sum_{v_2 \in \overline{E(H)}} w(v_2)) \\
< \sum_{v_1 \in Y} (w(v_1) \cdot w(V_2)) + \sum_{v_1 \in (V_1 \setminus Y)} (w(v_1) \cdot \frac{w(V_2)}{4}) \\
= w(Y) \cdot w(V_2) + w(V_1 \setminus Y) \cdot \frac{w(V_2)}{4} \\
\leq \frac{w(V_1)}{4} \cdot w(V_2) + w(V_1) \cdot \frac{w(V_2)}{4} = \frac{w(V_1) \cdot w(V_2)}{4},
\]
a contradiction. △

For a graph \( G \) given together with a weight function \( w : V(G) \rightarrow \mathbb{N} \), an optimum vertex cover of \( G \) is any vertex cover of \( G \) with the least total weight.
**The Algorithm**

An undirected graph $G$ is a **split graph** if its vertex set $V(G)$ can be partitioned into two parts, $V(G) = C \cup I$, such that $C$ is a clique and $I$ is an independent set in $G$. Such a partition is called a **split partition** of graph $G$. We use $(C, I)$ to denote such a split partition.

A **split vertex deletion set** of a graph $G$ is any subset $S \subseteq V(G)$ such that the graph $G - S$ obtained by deleting the vertices of $S$ from $G$, is a split graph. Note that any **vertex cover** of $G$ which leaves out at least two vertices of $G$ is a split vertex deletion set of $G$. This implies that every graph with at least two vertices has a (possibly empty) split vertex deletion set.

In the **Split Vertex Deletion (SVD)** problem the input consists of an undirected graph $G$ and a weight function $w : V(G) \to \mathbb{N}$ and the objective is to find a split vertex deletion set of $G$ of the smallest weight.

**Split Vertex Deletion (SVD)**

**Input:** An undirected graph $G$ and a weight function $w : V(G) \to \mathbb{N}$.

**Output:** A split vertex deletion set $S \subseteq V(G)$ of $G$ of the smallest weight (an optimum split vertex deletion set of $G$).

Since deleting vertices conserves the property of being a split graph one can safely add zero-weight vertices to any split vertex deletion set. So we assume without loss of generality that $w(v) \geq 1$ holds for every $v \in V(G)$. **Split Vertex Deletion** is **NP-complete** by the meta-result of Lewis and Yannakakis [9], and has a simple 5-factor approximation algorithm based on the Local Ratio Technique.

**Theorem 6.** There is a deterministic algorithm which, given an instance $(G, w)$ of **SVD**, runs in $O(|V(G)|^6)$ time and outputs a split vertex deletion set $S \subseteq V(G)$ of $G$ such that $w(S) \leq 5 \cdot w(OPT)$ where $OPT$ is an optimum split vertex deletion set of $G$.

**Proof.** A graph is a split graph if and only if does not contain any of the three graphs $\{2K_2, C_4, C_5\}$ as induced subgraphs [7]. Since the maximum order of these graphs is five and we can find each in $O(|V(G)|^5)$ time, a direct application of the Local Ratio Technique [3] gives a 5-factor approximate solution in $O(|V(G)|^6)$ time. ◊

We describe a randomized polynomial-time algorithm which outputs a $(2 + \varepsilon)$-factor approximate solution for this problem for any fixed $\varepsilon > 0$.

Note that in an instance $(G, w, (C, I, U))$ of **Annotated Split Vertex Deletion** the set $C$ is not necessarily a clique, nor is $I$ necessarily an independent set in $G$. But we have the following.

**Observation 7.** Let $S$ be a feasible solution of an **A-SVD** instance $(G, w, (C, I, U))$ and let $(C', I')$ be a split partition of $G - S$ where $C' \subseteq (C \cup U)$ and $I' \subseteq (I \cup U)$ hold. Then $C' \setminus S \subseteq C'$ and $I \setminus S \subseteq I'$ hold. Hence $C \setminus S$ is a clique in $G$ and $I \setminus S$ is an independent set in $G$.
From Observations 2 and 7 we get

**Corollary 8.** Let \( S \) be a feasible solution of an A-SVD instance \((G,w,(C,I,U)))\). Let \( VC_C \) be an optimum solution of the \( wV[C] \) instance \((G[w],w)\) and let \( VC_I \) be an optimum solution of the \( wV[C] \) instance \((G[I],w)\). Then \( w(VC_C) \leq w(S \cap C) \) and \( w(VC_I) \leq w(S \cap I) \) hold.

A-SVD is clearly a generalization of SVD: Given an instance \((G,w)\) of SVD, construct the instance \((G,w,(C=\emptyset,I=\emptyset,U=V(G)))\) of A-SVD. Every split vertex deletion set of graph \( G \) is a feasible solution of the A-SVD instance, and every annotated split vertex deletion set of \((G,w,(\emptyset,\emptyset,V(G)))\) is a split vertex deletion set of graph \( G \). It follows that for any constant \( c \), a \( c \)-factor approximate solution to the A-SVD instance is a \( c \)-factor approximate solution to the SVD instance as well.

We can find feasible solutions to an A-SVD instance \((G,w,(C,I,U)))\) by computing vertex covers for certain pairs of subgraphs derived from \( G \).

**Observation 9.** Let \((G,w,(C,I,U)))\) be an instance of A-SVD.

1. Let \( V_1 \) be a vertex cover of the graph \( G[I \cup U] \) and let \( V_2 \) be a vertex cover of the graph \( G[C] \). Then \( V_1 \cup V_2 \) is a feasible solution to \((G,w,(C,I,U)))\).

2. Let \( V_3 \) be a vertex cover of the graph \( G[I] \) and let \( V_4 \) be a vertex cover of the graph \( G[C \cup U] \). Then \( V_3 \cup V_4 \) is a feasible solution to \((G,w,(C,I,U)))\).

**Proof.** We prove each part in turn:

1. Let \( S = V_1 \cup V_2, I' = ((I \cup U) \setminus V_1), C' = (C \setminus V_2) \). Then \( I' \subseteq (I \cup U) \) and \( C' \subseteq (C \cup U) \) hold. Since \( V_1 \) is a vertex cover of the graph \( G[I \cup U] \) we get that \( I' \) is an independent set in \( G \). Since \( V_2 \) is a vertex cover of the graph \( G[C] \) we get that \( C' \) is a clique in \( G \).

Now \( V(G) \setminus S = (I \cup C \cup U) \setminus (V_1 \cup V_2) = ((I \cup U) \setminus V_1) \cup (C \setminus V_2) = I' \cup C' \). Hence \( S = V_1 \cup V_2 \) is a feasible solution to \((G,w,(C,I,U)))\).

2. Let \( S = V_3 \cup V_4, I' = (I \setminus V_3), C' = (C \setminus U) \setminus V_4 \). Then \( I' \subseteq (I \cup U) \) and \( C' \subseteq (C \cup U) \) hold. Since \( V_3 \) is a vertex cover of the graph \( G[I] \) we get that \( I' \) is an independent set in \( G \). Since \( V_4 \) is a vertex cover of the graph \( G[C \cup U] \) we get that \( C' \) is a clique in \( G \).

Now \( V(G) \setminus S = (I \cup C \cup U) \setminus (V_3 \cup V_4) = (I \setminus V_3) \cup (C \setminus U) \setminus V_4) = I' \cup C' \). Hence \( S = V_3 \cup V_4 \) is a feasible solution to \((G,w,(C,I,U)))\).

**Observation 10.** Let \((G,w,(C,I,U)))\) be an instance of A-SVD and let \( u \in U \).

1. Let \( V_1 \) be a vertex cover of the graph \( G[I \cup \{U \setminus \{u]\}] \) and let \( V_2 \) be a vertex cover of the graph \( G[C \cup \{u]\} \). Then \( V_1 \cup V_2 \) is a feasible solution to \((G,w,(C,I,U)))\).

2. Let \( V_3 \) be a vertex cover of the graph \( G[I \cup \{u]\} \) and let \( V_4 \) be a vertex cover of the graph \( G[C \cup \{U \setminus \{u]\}] \). Then \( V_3 \cup V_4 \) is a feasible solution to \((G,w,(C,I,U)))\).

**Proof.** We prove each part in turn:

1. Let \( S = V_1 \cup V_2, I' = ((I \cup \{U \setminus \{u]\}) \setminus V_1), C' = ((C \cup \{u\}) \setminus V_2) \). Then \( I' \subseteq (I \cup U) \) and \( C' \subseteq (C \cup U) \) hold. Since \( V_1 \) is a vertex cover of the graph \( G[I \cup \{U \setminus \{u]\}] \) we get that \( I' \) is an independent set in \( G \). Since \( V_2 \) is a vertex cover of the graph \( G[C \cup \{u]\} \) we get that \( C' \) is a clique in \( G \).

Now \( V(G) \setminus S = (I \cup C \cup U) \setminus (V_1 \cup V_2) = ((I \cup \{U \setminus \{u\}\}) \setminus V_1) \cup ((C \cup \{u\}) \setminus V_2) = I' \cup C' \). Hence \( S = V_1 \cup V_2 \) is a feasible solution to \((G,w,(C,I,U)))\).

2. Let \( S = V_3 \cup V_4, I' = (I \cup \{u\}) \setminus V_3), C' = (C \cup \{U \setminus \{u\}\}) \setminus V_4 \). Then \( I' \subseteq (I \cup U) \) and \( C' \subseteq (C \cup U) \) hold. Since \( V_3 \) is a vertex cover of the graph \( G[I \cup \{u\}] \) we get that \( I' \) is an independent set in \( G \). Since \( V_4 \) is a vertex cover of the graph \( G[C \cup \{U \setminus \{u\}\}] \) we get that \( C' \) is a clique in \( G \).

Now \( V(G) \setminus S = (I \cup C \cup U) \setminus (V_3 \cup V_4) = ((I \cup \{u\}) \setminus V_3) \cup ((C \cup \{U \setminus \{u\}\}) \setminus V_4) = I' \cup C' \). Hence \( S = V_3 \cup V_4 \) is a feasible solution to \((G,w,(C,I,U)))\).
Observation 9 has some interesting consequences. For instance, it implies that when the “unconstrained” set in an A-SVD instance is empty, an optimum solution to the A-SVD instance corresponds to optimum solutions of two Weighted Vertex Cover instances derived from the A-SVD instance in a natural fashion.

Lemma 11. Let $S^*$ be an optimum solution to an A-SVD instance $(G, w, (C, I, U = \emptyset))$. Then the set $(S^* \cap I)$ is an optimum solution to the wVC instance $(G[I], w)$, and the set $(S^* \cap C)$ is an optimum solution to the wVC instance $(G[C], w)$.

Proof. Since $S^*$ is a solution of the A-SVD instance $(G, w, (C, I, U = \emptyset))$, we get that the vertex set $V(G) \setminus S^* = (C \cup I) \setminus S^* = (C \setminus S^*) \cup (I \setminus S^*)$ can be partitioned into a clique $C^* \subseteq C$ and an independent set $I^* \subseteq I$. Since $U$ is the empty set we get that $I^* = I \setminus S^*$ and $C^* = C \setminus S^*$ hold. These in turn imply that $S^* \cap I$ is a vertex cover of the graph $G[I]$, and that $S^* \cap C$ is a vertex cover of the graph $G[C]$.

Suppose there exists a vertex cover $S' \subseteq I$ of the graph $G[I]$ with $w(S') < w(S^* \cap I)$. Since the set $S' \subseteq I$ is a vertex cover of the graph $G[I]$ and the set $(S^* \cap C) \subseteq C$ is a vertex cover of the graph $G[C]$ we get—Observation 9—that the set $\hat{S} = (S^* \cap C) \cup S'$ is a feasible solution to the instance $(G, w, (C, I, \emptyset))$. Now $w(\hat{S}) = w(S') + w(S^* \cap C) < w(S^* \cap I) + w(S^* \cap C) = w(S^*)$, and so $\hat{S}$ is a feasible solution with weight less than the weight of an optimum solution, a contradiction. It follows that $S^* \cap I$ is an optimum vertex cover of the graph $G[I]$ with the weight function $w$.

A symmetric argument shows that $S^* \cap C$ is an optimum vertex cover of the graph $G[C]$. Indeed, suppose $S' \subseteq C$ is a vertex cover of $G[C]$ with $w(S') < w(S^* \cap C)$. Since the set $(S^* \cap I) \subseteq I$ is a vertex cover of the graph $G[I]$ and the set $S' \subseteq C$ is a vertex cover of the graph $G[C]$ we get—Observation 9—that the set $\hat{S} = (S^* \cap I) \cup S'$ is a feasible solution to the instance $(G, w, (C, I, \emptyset))$. Now $w(\hat{S}) = w(S^* \cap I) + w(S') < w(S^* \cap I) + w(S^* \cap C) = w(S^*)$, and so $\hat{S}$ is a feasible solution with weight less than the weight of an optimum solution, a contradiction. It follows that $S^* \cap C$ is an optimum vertex cover of the graph $G[C]$ with the weight function $w$.

This in turn implies that given an A-SVD instance in which the unconstrained set $U$ is empty, we can find a 2-factor approximate solution to the instance in polynomial time.

Lemma 12. There is a deterministic algorithm which finds 2-factor approximate solutions to A-SVD instances which are of the form $(G, w, (C, I, U = \emptyset))$, in $\mathcal{O}(|E(G)|)$ time.

Proof. Let $(G, w, (C, I, U = \emptyset))$ be an instance of A-SVD. Note that $V(G) = C \cup I$. Recall that $G[C]$ denotes the complement of the graph $G[C]$, and that we use $w_I, w_C$ to denote the restrictions of the weight function $w$ to the vertex sets $I, C$, respectively. We drop the subscripts when there is no risk of ambiguity.

Given the input $(G, w, (C, I, U = \emptyset))$ the algorithm computes a 2-factor approximate solution $S_I$ to the wVC problem on the graph $G[I]$ with the weight function $w_I$, and a 2-factor approximate solution $S_C$ to the wVC problem on the graph $G[C]$ with the weight function $w_C$. It then returns the set $\hat{S} = S_I \cup S_C$ as a solution to the instance $(G, w, (C, I, U = \emptyset))$.

From Theorem 5 we get that this algorithm runs in $\mathcal{O}(|E(G)|)$ time. We show that it returns a 2-factor approximate solution. Since the set $S_I$ is a vertex cover of the graph $G[I]$ and the set $S_C$ is a vertex cover of the graph $G[C]$ we get—Observation 9—that the set $\hat{S} = S_I \cup S_C$ is a feasible solution to the instance $(G, w, (C, I, \emptyset))$. Let $S^*$ be an optimum solution to the instance $(G, w, (C, I, U = \emptyset))$. Then we have—Lemma 11—that $S^* \cap I$ is an optimum solution to the wVC problem on the graph $G[I]$ with the weight function $w_I$, and that $S^* \cap C$ is an optimum solution to the wVC problem on the graph $G[C]$ with the...
weight function $w_C$. So we get that $w(S_I) \leq 2w(S^* \cap I)$ and that $w(S_C) \leq 2w(S^* \cap C)$.
Therefore $w(\hat{S}) = w(S_I) + w(S_C) \leq 2w(S^* \cap I) + 2w(S^* \cap C) = 2w(S^*)$, and so $\hat{S}$ is a
2-factor approximate solution to the A-SVD instance $(G, w, (C, I, U = \emptyset))$. ∧

This idea generalizes as follows. Let $OPT$ be an optimum solution to an A-SVD instance $(G, w, (C, I, U))$. Suppose the split graph $G - OPT$ has a split partition $(C^*, I^*)$ such that vertices from the unconstrained set $U$ contribute a small weight to either the clique $C^*$ or the independent set $I^*$. Then a variant of the algorithm in the proof of Lemma 12 yields a small-factor approximate solution to the instance, in polynomial time. We state this formally in Lemma 16 below, for which we need some notation (see Figure 1).

Definition 13. Let $(G, w, (C, I, U))$ be an instance of A-SVD, and let $\varepsilon \geq 0$ be a constant.
Let $OPT \subseteq V(G)$ be an optimum solution of $(G, w, (C, I, U))$ and let $(C^*, I^*)$ be a split
partition of the split graph $G^* = (G - OPT)$ such that $C^* \subseteq (C \cup U)$ and $I^* \subseteq (I \cup U)$
hold. Let $C^*_U = (C^* \cap U)$ be the set of vertices from the unconstrained set $U$ which become
part of the clique $C^*$ and let $I^*_U = (I^* \cap U)$ be the set of vertices from $U$ which become
part of the independent set $I^*$ in $G^*$. Let $U_{OPT} = (U \cap OPT)$, $C_{OPT} = (C \cap OPT)$ and
$I_{OPT} = (I \cap OPT)$.

Further, let $X$ be a 5-factor approximate solution of the Split Vertex Deletion instance $(G[U], w_U)$ defined by the induced subgraph $G[U]$, and let $(C_X, I_X)$ be a split
partition of the split graph $G[U] - X$.

Remark 14. Given an instance $(G, w, (C, I, U))$ of A-SVD we can, using Theorem 6, compute
such a set $X$ and partition $(C_X, I_X)$ in polynomial time.

Observation 15. Let $(G, w, (C, I, U))$, $X, I_X, C_X, I_U, C_U$ be as in Definition 13. Then both
$|I^*_U \setminus (X \cup (I_X \setminus C^*_U))| \leq 1$ and $|C^*_U \setminus (X \cup (C_X \setminus I^*_U))| \leq 1$ hold.

Proof. Since $I^*_U \cap C^*_U = \emptyset$ holds we get that $I^*_U \setminus (X \cup (I_X \setminus C^*_U)) = I^*_U \setminus (X \cup I_X) = I^*_U \cap C_X$.
And since $I^*_U$ is an independent set and $C_X$ is a clique we get that $|I^*_U \cap C_X| \leq 1$ holds.
Similarly, since $C^*_U \cap I^*_U = \emptyset$ holds we get that $C^*_U \setminus (X \cup (C_X \setminus I^*_U)) = C^*_U \setminus (X \cup C_X) =$
$C^*_U \cap I_X$. And since $C^*_U$ is a clique and $I_X$ is an independent set we get that $|C^*_U \cap I_X| \leq 1$
holds. ∧
Lemma 16. Let \((G, w, (C, I, U)), \varepsilon, OPT, C'_U, I'_U\) be as in Definition 13. Let \(S_1\) be a 2-factor approximate solution for the \(wVC\) instance \((G[I \cup U], w)\) and \(S_2\) a 2-factor approximate solution for the \(wVC\) instance \((G[C], w)\). Let \(S_{12} = (S_1 \cup S_2)\). Let \(S_3\) be a 2-factor approximate solution for the \(wVC\) instance \((G[C \cup U], w)\) and \(S_4\) a 2-factor approximate solution for the \(wVC\) instance \((G[I], w)\). Let \(S_{34} = (S_3 \cup S_4)\). Then the sets \(S_{12}\) and \(S_{34}\) can be computed in \(O(|E(G)|)\) time. Further,

1. If \(w(C'_U) \leq \frac{\varepsilon w(OPT)}{2}\) holds then the set \(S_{12}\) is a \((2 + \varepsilon)\)-factor approximate solution for the Annotated Split Vertex Deletion instance \((G, w, (C, I, U))\).

2. If \(w(I'_U) \leq \frac{\varepsilon w(OPT)}{2}\) holds then the set \(S_{34}\) is a \((2 + \varepsilon)\)-factor approximate solution for the Annotated Split Vertex Deletion instance \((G, w, (C, I, U))\).

Remark 17. Note that these two cases are neither exclusive nor exhaustive.

Proof. From Theorem 5 we get that the sets \(S_1, S_2, S_3, S_4\) all can be computed in \(O(|E(G)|)\) time. Hence we get that the sets \(S_{12}\) and \(S_{34}\) can be computed in \(O(|E(G)|)\) time as well.

The two cases are symmetric; we prove each case in turn.

1. From part (1) of Observation 9 we get that the set \((S_1 \cup S_2)\) is a feasible solution to the A-SVD instance \((G, w, (C, I, U))\). We now show that \((S_1 \cup S_2)\) is a \((2 + \varepsilon)\)-factor approximate solution to \((G, w, (C, I, U))\).

Observe first that \(((C \cup U) \setminus OPT) = I \cup C'_U\). From this, and since \(I^*\) is an independent set in \(G\), we get that the set \((OPT \cap (C \cup U)) \cup C'_U = (OPT \setminus C_{OPT}) \cup C'_U\) is a vertex cover of the graph \(G[C \cup U]\), of weight \(w(OPT) - w(C_{OPT}) + w(C'_U) \leq w(OPT) - w(C_{OPT}) + \varepsilon \frac{w(OPT)}{2}\).

Thus an optimum vertex cover of the graph \(G[I \cup U]\) has weight at most \(w(OPT)(1 + \frac{\varepsilon}{2}) - w(C_{OPT})\), and since \(S_1\) is a 2-factor approximate vertex cover for \(G[I \cup U]\) we get that \(w(S_1) \leq 2w(OPT)(1 + \frac{\varepsilon}{2}) - 2w(C_{OPT})\) holds. From Corollary 8 we know that an optimum vertex cover of the graph \(G[C]\) has weight at most \(w(C_{OPT})\), and since \(S_2\) is a 2-factor approximate vertex cover for \(G[C]\) we get that \(w(S_2) \leq 2w(C_{OPT})\) holds. Thus together we get that \(w(S_1 \cup S_2) \leq 2w(OPT)(1 + \frac{\varepsilon}{2}) - 2w(C_{OPT}) + 2w(C_{OPT}) = (2 + \varepsilon)w(OPT)\), and this completes the proof.

2. From part (2) of Observation 9 we get that the set \((S_3 \cup S_4)\) is a feasible solution to the A-SVD instance \((G, w, (C, I, U))\). We now show that \((S_3 \cup S_4)\) is a \((2 + \varepsilon)\)-factor approximate solution to \((G, w, (C, I, U))\).

Observe first that \(((C \cup U) \setminus OPT) = C^* \cup I'_U\). From this, and since \(C^*\) is an independent set in \(G\), we get that the set \((OPT \cap (C \cup U)) \cup I'_U = (OPT \setminus I_{OPT}) \cup I'_U\) is a vertex cover of the graph \(G[C \cup U]\), of weight \(w(OPT) - w(I_{OPT}) + w(I'_U) \leq w(OPT) - w(I_{OPT}) + \varepsilon \frac{w(OPT)}{2}\).

Thus an optimum vertex cover of the graph \(G[C \cup U]\) has weight at most \(w(OPT)(1 + \frac{\varepsilon}{2}) - w(I_{OPT})\), and since \(S_3\) is a 2-factor approximate vertex cover for \(G[C \cup U]\) we get that \(w(S_3) \leq 2w(OPT)(1 + \frac{\varepsilon}{2}) - 2w(I_{OPT})\) holds. From Corollary 8 we know that an optimum vertex cover of the graph \(G[I]\) has weight at most \(w(I_{OPT})\), and since \(S_4\) is a 2-factor approximate vertex cover for \(G[I]\) we get that \(w(S_4) \leq 2w(I_{OPT})\) holds. Putting these together we get that \(w(S_3 \cup S_4) \leq 2w(OPT)(1 + \frac{\varepsilon}{2}) - 2w(I_{OPT}) + 2w(I_{OPT}) = (2 + \varepsilon)w(OPT)\), and this completes the proof.

By repeatedly applying the procedure in the proof of Lemma 16 and taking the minimum, we can find a \((2 + \varepsilon)\)-factor approximate solution in polynomial time even in the more general case where there is at most one “heavy” vertex in \(C'_U\) or \(I'_U\).

Lemma 18. Let \((G, w, (C, I, U)), \varepsilon, OPT, C'_U, I'_U\) be as in Definition 13. For each vertex \(u \in U\) let \(S_u^a\) be a 2-factor approximate solution for the \(wVC\) instance \((G[I \cup U \setminus \{u\}], w), S_u^a\) a 2-factor approximate solution for the \(wVC\) instance \((G[C \cup \{u\}], w), S_u^a\) a 2-factor approximate solution for the \(wVC\) instance \((G[C \cup (U \setminus \{u\}], w), S_u^a\) a
2-factor approximate solution for the \( wVC \) instance \( (G[I \cup \{u\}], w) \), and let \( S^u_{34} = S^u_3 \cup S^u_4 \).

Finally, let \( S^i \) be a set of the form \( S^i_{2} \) of the minimum weight and let \( S^i \) be a set of the form \( S^i_{34} \) of the minimum weight, both minima taken over all vertices \( u \in U \).

The sets \( S^i \) and \( S^i \) can be computed in \( O(|V(G)| \cdot |E(G)|) \) time. Further,

1. If \( w(C_U^0 \setminus \{c^*\}) \leq \frac{\epsilon \cdot w(OPT)}{2} \) holds for some vertex \( c^* \in C_U^0 \), then the set \( S^i \) is a \((2+\epsilon)\)-factor approximate solution for the A-SVD instance \( (G, w, (C, I, U)) \).

2. If \( w(I_U^0 \setminus \{i^*\}) \leq \frac{\epsilon \cdot w(OPT)}{2} \) holds for some vertex \( i^* \in I_U^0 \), then the set \( S^i \) is a \((2+\epsilon)\)-factor approximate solution for the A-SVD instance \( (G, w, (C, I, U)) \).

\(\triangleright\) **Remark 19.** Note that these two cases are neither exclusive nor exhaustive.

**Proof.** From Theorem 5 we get that for each vertex \( u \in U \) the sets \( S^u_1, S^u_2, S^u_3, S^u_4 \) can all be computed in \( O(|E(G)|) \) time. Hence we get that the sets \( S^i \) and \( S^i \) can be computed in \( O(|V(G)| \cdot |E(G)|) \) time.

The two cases are symmetric; we prove each case in turn.

1. Let \( S_1 \) be a 2-factor approximate solution for the \( wVC \) instance \( (G[I \cup \{u\}], w) \), let \( S_2 \) be a 2-factor approximate solution for the \( wVC \) instance \( (G[C \cup \{c^*\}], w) \), and let \( S^* = (S_1 \cup S_2) \). From part (2) of Observation 10 we get that the set \( S^* \) is a feasible solution to the A-SVD instance \( (G, w, (C, I, U)) \).

\(\triangleright\) **Claim 19.1.** \( S^* \) is a \((2+\epsilon)\)-factor approximate solution to \( (G, w, (C, I, U)) \).

**Proof.** Recall that by assumption the vertex \( c^* \) belongs to the set \( C_U^0 \). This implies, in particular—see Definition 13—that \( c^* \) is not in the set \( OPT \).

Observe first that \( ((I \cup \{c^*\}) \setminus OPT) \cup OPT = I^* \cup (C_U^0 \setminus \{c^*\}) \). From this, and since \( I^* \) is an independent set in \( G \), we get that the set \( OPT \cap (I \cup \{c^*\}) \cup (C_U^0 \setminus \{c^*\}) \) is a vertex cover of the graph \( G[I \cup \{c^*\}] \), of weight \( w(OPT) - w(COPT) + w(C_U^0 \setminus \{c^*\}) \leq w(OPT) - w(COPT) + \frac{\epsilon \cdot w(OPT)}{2} \). Thus an optimum vertex cover of the graph \( G[I \cup \{c^*\}] \) has weight at most \( w(OPT)(1 + \frac{\epsilon}{2}) - w(COPT) \), and since \( S_1 \) is a 2-factor approximate vertex cover for \( G[I \cup \{c^*\}] \) we get that \( w(S_1) \leq 2w(OPT)(1 + \frac{\epsilon}{2}) - 2w(COPT) \) holds.

Since the sets \( C \setminus COP_T \) and \( C_U^0 \) are subsets of the clique \( C^* \) and since \( c^* \in C_U^0 \) holds by assumption, we get that the set \( (C \setminus COP_T) \cup \{c^*\} \) is a clique in \( G \). It follows that the set \( COP_T \) is a vertex cover of the induced subgraph \( G[C \cup \{c^*\}] \). Thus we get that an optimum vertex cover of the graph \( G[C \cup \{c^*\}] \) has weight at most \( w(COPT) \), and since \( S_2 \) is a 2-factor approximate vertex cover for \( G[C \cup \{c^*\}] \) we get that \( w(S_2) \leq 2w(COPT) \) holds. Putting these together we get that \( w(S_1 \cup S_2) \leq 2w(OPT)(1 + \frac{\epsilon}{2}) - 2w(COPT) + 2w(COPT) = (2+\epsilon)w(OPT) \). Thus \( S^* \) is a \((2+\epsilon)\)-factor approximate solution to \( (G, w, (C, I, U)) \).

\(\triangleright\)

Since \( S^i \) is a set of the minimum weight of the form \( S^u_{12} : u \in U \), we get from Claim 19.1 that \( S^i \) is a \((2+\epsilon)\)-factor approximate solution for \( (G, w, (C, I, U)) \).

2. Let \( S_1 \) be a 2-factor approximate solution for the \( wVC \) instance \( (G[C \cup \{i^*\}], w) \), let \( S_2 \) be a 2-factor approximate solution for the \( wVC \) instance \( (G[I \cup \{i^*\}], w) \), and let \( S^* = (S_1 \cup S_1) \). From part (2) of Observation 10 we get that the set \( S^* \) is a feasible solution to the A-SVD instance \( (G, w, (C, I, U)) \).

\(\triangleright\) **Claim 19.2.** \( S^* \) is a \((2+\epsilon)\)-factor approximate solution to \( (G, w, (C, I, U)) \).
Proof. Recall that by assumption the vertex $i^*$ belongs to the set $I_U^\ast$. This implies, in particular—see Definition 13—that $i^*$ is not in the set $OPT$.

Observe first that \((C \cup (U \setminus \{i^*\})) \setminus OPT = C^* \cup (I_U \setminus \{i^*\})\). From this, and since $C^*$ is an independent set in $G$, we get that the set \((OPT \cap (C \cup (U \setminus \{i^*\})) \cup (I_U \setminus \{i^*\}) = (OPT \cap (C \cup U)) \cup (I_U \setminus \{i^*\}) = (OPT \setminus IOPT) \cup (I_U \setminus \{i^*\})\) is a vertex cover of the graph $G(C \cup (U \setminus \{i^*\}))$, of weight $w(OPT) - w(IOPT) + w(I_U \setminus \{i^*\}) \leq w(OPT) - w(IOPT) + \frac{\varepsilon w(OPT)}{2}$. Thus an optimum vertex cover of the graph $G[C \cup (U \setminus \{i^*\})]$ has weight at most $w(OPT)(1 + \frac{\varepsilon}{2}) - w(IOPT)$, and since $S_3$ is a 2-factor approximate vertex cover for $G[C \cup (U \setminus \{i^*\})]$ we get that $w(S_3) \leq 2w(OPT)(1 + \frac{\varepsilon}{2}) - 2w(IOPT)$ holds.

Since $I \setminus IOPT$ and $I_U^\ast$ are subsets of the independent set $I^\ast$ and since $i^* \in I_U^\ast$ holds by assumption, we get that the set \((I \setminus IOPT) \cup \{i^*\}\) is an independent set in $G$. It follows that the set $I_{OPT}$ is a vertex cover of the induced subgraph $G[I \cup \{i^*\}]$.

Thus we get that an optimum vertex cover of the graph $G[I \cup \{i^*\}]$ has weight at most $w(I_{OPT})$, and since $S_3$ is a 2-factor approximate vertex cover for $G[I \cup \{i^*\}]$, we get that $w(S_3) \leq 2w(I_{OPT})$ holds. Putting these together we get that $w(S_3 \cup S_4) \leq 2w(OPT)(1 + \frac{\varepsilon}{2}) - 2w(I_{OPT}) + 2w(I_{OPT}) = (2 + \varepsilon)w(OPT)$. Thus $S^\ast$ is a $(2 + \varepsilon)$-factor approximate solution to $(G, w, (C, I, U))$. \hfill \(

Since $S^\ast$ is a set of the minimum weight of the form $S^\ast_{u, \ast} : u \in U$, we get from Claim 19.2 that $S^\ast$ is a $(2 + \varepsilon)$-factor approximate solution for $(G, w, (C, I, U))$. \hfill \(\triangleleft

\textbf{Definition 20.} Let $(G, w, (C, I, U)), \varepsilon, OPT, C^*, I^*, C_U^*, I_U^\ast$ be as in Definition 13. We say that $(G, w, (C, I, U))$ is an easy instance if $U = \emptyset$ holds, or if at least one of the following holds: (i) $w(C_U^* \setminus I_U^\ast) \leq \frac{\varepsilon w(OPT)}{2}$, (ii) $w(I_U^\ast) \leq \frac{\varepsilon w(OPT)}{2}$, (iii) $w(C_U^* \setminus \{c^\ast\}) \leq \frac{\varepsilon w(OPT)}{2}$ holds for some vertex $c^\ast \in C_U^*$, (iv) $w(I_U^\ast \setminus \{i^\ast\}) \leq \frac{\varepsilon w(OPT)}{2}$ holds for some vertex $i^\ast \in I_U^\ast$. We say that $(G, w, (C, I, U))$ is a hard instance otherwise.

From Lemma 12, Lemma 16 and Lemma 18 we get

\textbf{Corollary 21.} There is an algorithm which, given an easy instance $(G, w, (C, I, U))$ of A-SVD and a constant $\varepsilon > 0$ as input, computes a $(2 + \varepsilon)$-factor approximate solution for $(G, w, (C, I, U))$ in deterministic polynomial time.

\textbf{Lemma 22.} Let $(G, w, (C, I, U))$ be a hard instance of A-SVD and let $\varepsilon, C_U^*, I_U^\ast, X, \text{IX}, C_X$ be as in Definition 13. Then the following hold:

1. $w(X \cup (I_X \setminus C_X^*) < (1 + \frac{12}{\varepsilon}) \cdot w(I_U^\ast)$
2. $w(X \cup (C_X \setminus I_U^-)) < (1 + \frac{12}{\varepsilon}) \cdot w(C_U^*)$

\textbf{Proof.} Let $OPT, U_{OPT}, I_{OPT}$ be as in Definition 13. Then $w(U_{OPT}) \leq w(OPT)$ and $w(I_{OPT}) \leq w(OPT)$ hold trivially. From Definition 13 we get that $w(X) \leq 5w(OPT)$ holds, and since $I_X, C_X$ are subsets of $U$ and $I_U^\ast \cup C_U^* \cup U_{OPT}$ is a partition of $U$ we get that both $(I_X \setminus C_X^*) \subseteq (I_U^\ast \cup U_{OPT})$ and $(C_X \setminus I_U^-) \subseteq (C_U^* \cup U_{OPT})$ hold. Finally, since $(G, w, (C, I, U))$ is a hard instance of A-SVD we have—Definition 20—that both $w(OPT) < \frac{2w(I_U^\ast)}{\varepsilon}$ and $w(OPT) < \frac{2w(C_U^*)}{\varepsilon}$ hold.

Hence we get

\begin{align*}
w(X \cup (I_X \setminus C_X^*)) & = w(X) + w(I_X \setminus C_X^*) \leq 5w(OPT) + w(I_U^\ast \cup U_{OPT}) \\ & = 5w(OPT) + w(I_U^\ast) + w(U_{OPT}) \leq 6w(OPT) + w(I_U^\ast) \\ & < (1 + \frac{12}{\varepsilon})w(I_U^\ast).
\end{align*}
Similarly,
\[
\begin{align*}
  w(X \cup (C_X \setminus I^*_U)) &= w(X) + w(C_X \setminus I^*_U) \\
  &= w(OPT) + w(C^*_U \cup U_{OPT}) \\
  &< (1 + \frac{12}{\varepsilon})w(C^*_U).
\end{align*}
\]

Recall the notion of heavy and light pairs from Definition 3.

**Lemma 23.** Let \((G, w, (C, I, U))\) be a hard instance of \(A\text{-SVD} \) and let \(\varepsilon, OPT, C^*, I^*, C^*_U, I^*_U\) be as in Definition 13. Suppose \((I^*_U, C^*_U)\) is a heavy pair. Let \(I^\circ = \{v \in I^*_U : w(N(v) \cap C^*_U) \geq w(C^*_U) / 4\}\) be the set of vertices in \(I^*_U\) which have a “heavy” neighbourhood in \(C^*_U\), and let \(I^\circ\) be a heaviest vertex in \(I^\circ\). Let \(C^\circ = \{v \in C^*_U : w((I^*_U \setminus \{i^\circ\}) \setminus (N(v) \cap I^*_U)) \geq \frac{w(I^*_U \setminus \{i^\circ\})}{4}\}\) be the set of vertices in \(C^*_U\) which have a “heavy” non-neighbourhood in the subset \(I^*_U \setminus \{i^\circ\}\), and let \(C^\circ\) be a heaviest vertex in \(C^\circ\). Let \(I^\circ = \{v \in (I^*_U \setminus \{i^\circ\}) : w(N(v) \cap (C^*_U \setminus \{c^\circ\})) \geq \frac{w(I^*_U \setminus \{i^\circ\})}{4}\}\) be the set of vertices in \(I^*_U \setminus \{i^\circ\}\) which have a “heavy” neighbourhood in \(C^*_U \setminus \{c^\circ\}\), and let \(C^\circ = \{v \in (C^*_U \setminus \{c^\circ\}) : w((I^*_U \setminus \{i^\circ\}) \setminus (N(v) \cap I^*_U)) \geq \frac{w(I^*_U \setminus \{i^\circ\})}{4}\}\) be the set of vertices in \((C^*_U \setminus \{c^\circ\})\) which have a “heavy” non-neighbourhood in \(I^*_U \setminus \{i^\circ\}\).

Then at least one of the following statements holds:

\(a (1a)\) Picking a vertex proportionately at random from the set \(X \cup (I_X \setminus C^*_U)\) yields a vertex \(v \in I^\circ\) with probability at least \(1/(20(1 + \frac{12}{\varepsilon}))\).

\(a (1b)\) Picking a vertex proportionately at random from the set \(X \cup (I_X \setminus C^*_U)\) yields a vertex \(v \in I^\circ\) with probability at least \(1/(4(1 + \frac{12}{\varepsilon}))\).

\(a (2a)\) Picking a vertex proportionately at random from the set \(X \cup (C_X \setminus I^*_U)\) yields a vertex \(v \in C^\circ\) with probability at least \(1/(20(1 + \frac{12}{\varepsilon}))\).

\(a (2b)\) Picking a vertex proportionately at random from the set \(X \cup (C_X \setminus I^*_U)\) yields a vertex \(v \in C^\circ\) with probability at least \(1/(4(1 + \frac{12}{\varepsilon}))\).

**Proof.** We structure the proof as a number of short claims.

\(\blacktriangleright \) Claim 23.1. \(w(X \cup (I_X \setminus C^*_U)) < 4(1 + \frac{12}{\varepsilon}) \cdot w(I^\circ)\)

Proof. Since \((I^*_U, C^*_U)\) is a heavy pair we get from Lemma 4 that \(w(I^\circ) > \frac{w(I^*_U)}{4}\) holds.

Since \((G, w, (C, I, U))\) is a hard instance we get from Lemma 22 that \(w(X \cup (I_X \setminus C^*_U)) < (1 + \frac{12}{\varepsilon}) \cdot w(I^*_U)\) holds. Putting these together we get the claim.

\(\blacktriangleright \) Claim 23.2. If \(w(I^\circ) < \frac{4w(I^\circ)}{9}\) holds then part \((1a)\) of the lemma holds.

Proof. If \(I^\circ \subseteq X \cup (I_X \setminus C^*_U)\) holds then from Claim 23.1 we get that part \((1a)\) of the lemma holds.

So suppose \(I^\circ \nsubseteq X \cup (I_X \setminus C^*_U)\) holds. Then we get from Observation 15 that \(|I^\circ \setminus (X \cup (I_X \setminus C^*_U))| = 1\) holds. Since a heaviest vertex in \(I^\circ\) has weight less than \(\frac{4w(I^\circ)}{9}\) we get that \(w(I^\circ \setminus (X \cup (I_X \setminus C^*_U))) < \frac{4w(I^\circ)}{9}\) holds as well. Hence \(w(I^\circ \cap (X \cup (I_X \setminus C^*_U))) > \frac{w(I^\circ)}{9}\) holds, and using Claim 23.1 we get that picking a vertex proportionately at random from the set \(X \cup (I_X \setminus C^*_U)\) yields a vertex from the set \(I^\circ \cap (X \cup (I_X \setminus C^*_U))\) with probability more than \(1/20(1 + \frac{12}{\varepsilon})\), which satisfies part \((1a)\) of the lemma.

From now on we assume that \(w(I^\circ) \geq \frac{4w(I^\circ)}{9}\) holds. If \(i^\circ \in X \cup (I_X \setminus C^*_U)\) holds, then from Claim 23.1 and our assumption about \(w(I^\circ)\) we get that picking a vertex proportionately at random from the set \(X \cup (I_X \setminus C^*_U)\) yields the vertex \(i^\circ\) itself with probability at least \(1/5(1 + \frac{12}{\varepsilon})\), which satisfies part \((1a)\) of the lemma. So from now on we assume that \(i^\circ \notin X \cup (I_X \setminus C^*_U)\) holds.
Claim 23.3. If \((I_U^c \setminus \{c\}), C_U^c\) is a heavy pair then part (1a) of the lemma holds.

Proof. Since \((I_U^c \setminus \{c\}), C_U^c\) is a heavy pair we get from Lemma 4 that \(w(I^C \cap (I_U^c \setminus \{c\})) > w(C_U^c \setminus \{c\})\) holds. It follows that if we pick a vertex from the set \(I_U^c \setminus \{c\}\) proportionally at random with probability \(p\) then we get a vertex from the set \(I^C\) with probability more than \(\frac{p}{2}\).

Since \(c \notin X \cup (I_U \setminus C_U^c)\) holds, from Observation 15 we get that \((I_U^c \setminus \{c\}) \subseteq X \cup (I_U \setminus C_U^c)\) holds. Observe that, in general, \((X \setminus C_U^c) \subseteq (I_U \cup U_{OPT})\) holds. In this case since the vertex \(i^C \in I_U^c\) is not in the set \(I_U \setminus C_U^c\) we get that \((X \setminus C_U^c) \subseteq ((I_U^c \setminus \{c\}) \cup U_{OPT})\) holds. Hence we get that \(w(X \cup (I_U \setminus C_U^c)) \leq w(X) + w(I_U^c \setminus \{c\}) + w(U_{OPT}) \leq 6w(OPT) + w(I_U^c \setminus \{c\})\) holds in this case. Also, since \((G, w, (C, I, U))\) is a hard instance we get—Definition 20—that \(w(I_U^c \setminus \{c\}) > \frac{6w(OPT)}{2}\) holds. Putting these together we get

\[
\frac{w(X \cup (I_U \setminus C_U^c))}{w(I_U^c \setminus \{c\})} \leq 1 + \frac{6w(OPT)}{w(I_U^c \setminus \{c\})} = 1 + \frac{\epsilon}{\epsilon},
\]

Thus we get that \(w(X \cup (I_U \setminus C_U^c)) < (1 + \frac{\epsilon}{2})w(I_U^c \setminus \{c\})\) holds. It follows that picking a vertex proportionately at random from the set \(X \cup (I_U \setminus C_U^c)\) yields a vertex from the set \(I_U^c \setminus \{c\}\) with probability more than \(\frac{1}{1 + \frac{\epsilon}{2}}\). And this vertex is in the set \(I^C\) with probability more than \(\frac{1}{4}(1 + \frac{\epsilon}{2})\), which satisfies part (1a) of the lemma.

From now on we assume that \((I_U^c \setminus \{c\}), C_U^c\) is a light pair.

Claim 23.4. \(w(X \cup (C_X \setminus I_U^c)) < 4(1 + \frac{\epsilon}{2}) \cdot w(C^C)\)

Proof. Since \((I_U^c \setminus \{c\}), C_U^c\) is a light pair we get from Lemma 4 that \(w(C^C) > \frac{w(C_U^c \setminus \{c\})}{4}\) holds. Since \((G, w, (C, I, U))\) is a hard instance we get from Lemma 22 that \(w(X \cup (C_X \setminus I_U^c)) < (1 + \frac{\epsilon}{2}) \cdot w(C_U^c)\) holds. Putting these together we get the claim.

Claim 23.5. If \(w(c^C) < \frac{4w(C^C)}{5}\) holds then part (2a) of the lemma holds.

Proof. If \(C^C \subseteq X \cup (C_X \setminus I_U^c)\) holds then from Claim 23.4 we get that part (2a) of the lemma holds.

So suppose \(C^C \not\subseteq X \cup (C_X \setminus I_U^c)\) holds. Then we get from Observation 15 that \(|C^C \setminus (X \cup (C_X \setminus I_U^c))| = 1\) holds. Since a heaviest vertex in \(C^C\) has weight less than \(\frac{4w(C^C)}{5}\) we get that \(w(C^C \setminus (X \cup (C_X \setminus I_U^c))) < \frac{4w(C^C)}{5}\) holds as well. Hence \(w(C^C \cap (X \cup (C_X \setminus I_U^c))) > \frac{w(C^C)}{5}\) holds, and using Claim 23.4 we get that picking a vertex proportionately at random from the set \(X \cup (C_X \setminus I_U^c)\) yields a vertex from the set \(C^C \cap (X \cup (C_X \setminus I_U^c))\) with probability more than \(\frac{1}{20}(1 + \frac{\epsilon}{2})\), which satisfies part (2a) of the lemma.

From now on we assume that \(w(c^C) \geq \frac{4w(C^C)}{5}\) holds. If \(c^C \in X \cup (C_X \setminus I_U^c)\) holds then from Claim 23.4 and our assumption about \(w(c^C)\) we get that picking a vertex proportionately at random from the set \(X \cup (C_X \setminus I_U^c)\) yields the vertex \(c^C\) itself with probability at least \(\frac{1}{5}(1 + \frac{\epsilon}{2})\), which satisfies part (2a) of the lemma. So from now on we assume that \(c^C \notin X \cup (C_X \setminus I_U^c)\) holds.

Claim 23.6. If \(((I_U^c \setminus \{c\}), C_U^c \setminus \{c\})\) is a heavy pair then part (1b) of the lemma holds.
Proof. Since \((I^C_C, C_U^C \setminus \{e^C\})\) is a heavy pair we get from Lemma 4 that \(w(I^C_C \cap
(I^C_C \setminus \{e^C\})) \cdot \frac{1}{4} \geq w(I^C_C \setminus \{e^C\})\) holds. It follows that if we pick a vertex from the set \(I^C_C \setminus \{e^C\}\) proportionately at random with probability \(p\) then we get a vertex from the set \(I^C_C\) with probability more than \(\frac{p}{3}\).

Applying the exact same argument as in the proof of Claim 23.3 we get that picking a vertex proportionately at random from the set \(X \cup (I^C_C \setminus C_U^C)\) yields a vertex from the set \(I^C_C \setminus \{e^C\}\) with probability more than \(1/(1 + \frac{12}{\varepsilon})\). This vertex is in the set \(I^C_C\) with probability more than \(1/4(1 + \frac{12}{\varepsilon})\), which satisfies part (1b) of the lemma. \(\triangle\)

From Lemma 4 we get that in the remaining case \((I^C_C \setminus \{e^C\}, C_U^C \setminus \{e^C\})\) is a light pair.

Claim 23.7. If \((I^C_C \setminus \{e^C\}, C_U^C \setminus \{e^C\})\) is a light pair then part (2b) of the lemma holds.

Proof. Since \((I^C_C \setminus \{e^C\}, C_U^C \setminus \{e^C\})\) is a light pair we get from Lemma 4 that \(w(C^C \cap C_U^C \setminus \{e^C\}) > \frac{w(C^C \setminus \{e^C\})}{4}\) holds. It follows that if we pick a vertex from the set \(C^C \setminus \{e^C\}\) proportionately at random with probability \(p\) then we get a vertex from the set \(C^C\) with probability more than \(\frac{p}{4}\).

Since \(e^C \notin X \cup (C_X \setminus I^C_C)\) holds, from Observation 15 we get that \((C_U^C \setminus \{e^C\}) \subseteq X \cup (C_X \setminus I^C_C)\) holds. Observe that, in general, \((C_X \setminus I^C_C) \subseteq (C_U^C \cup U_{OPT})\) holds. In this case since the vertex \(e^C \in C_U^C\) is not in the set \(X \setminus I^C_C\) we get that \((C_X \setminus I^C_C) \subseteq (C_U^C \setminus \{e^C\}) \cup U_{OPT}\) holds. Hence we get that \(w(X \cup (C_X \setminus I^C_C)) \leq w(X) + w(C_U^C \setminus \{e^C\}) + w(U_{OPT}) \leq 6w(OPT) + w(C_U^C \setminus \{e^C\})\) holds in this case. Also, since \((G, w, (C, I, U))\) is a hard instance we get—Definition 20—that \(w(C_U^C \setminus \{e^C\}) > \frac{w(OPT)}{2}\) holds. Putting these together we get

\[
\frac{w(X \cup (C_X \setminus I^C_C))}{w(C_U^C \setminus \{e^C\})} \leq 6w(OPT) + w(C_U^C \setminus \{e^C\}) = 1 + \frac{6w(OPT)}{w(C_U^C \setminus \{e^C\})} < 1 + \frac{6w(OPT)}{\frac{w(OPT)}{2}} = \frac{\varepsilon + 12}{\varepsilon}.
\]

Thus we get that \(w(X \cup (C_X \setminus I^C_C)) < (1 + \frac{12}{\varepsilon})w(C_U^C \setminus \{e^C\})\) holds. It follows that picking a vertex proportionately at random from the set \(X \cup (C_X \setminus I^C_C)\) yields a vertex from the set \(C_U^C \setminus \{e^C\}\) with probability more than \(1/(1 + \frac{12}{\varepsilon})\). This vertex is in the set \(C^C\) with probability more than \(1/4(1 + \frac{12}{\varepsilon})\), which satisfies part (2b) of the lemma. \(\triangle\)

Thus, assuming \((C_U^C, I^C_C)\) is a heavy pair, at least one of the statements is always true. \(\triangle\)

Lemma 24. Let \((G, w, (C, I, U))\) be a hard instance of A-SVD and let \(\varepsilon, OPT, C^*, I^*, C_U^C, I^C_C\) be as in Definition 13. Suppose \((I^C_C, C_U^C)\) is a light pair. Let \(C^\parallel = \{v \in C_U^C : w(I^C_C \setminus (N(v) \cap I^C_C)) \geq \frac{w(I^C_C)}{4}\}\) be the set of vertices in \(C_U^C\) which have a “heavy” non-neighbourhood in \(I^C_C\), and let \(c^\parallel\) be a heaviest vertex in \(C^\parallel\). Let \(I^\parallel = \{v \in I^C_C : w(N(v) \cap (C_U^C \setminus \{c^\parallel\})) \geq \frac{w(C_U^C \setminus \{c^\parallel\})}{4}\}\) be the set of vertices in \(I^C_C\) which have a “heavy” neighbourhood in the subset \(C_U^C \setminus \{c^\parallel\}\), and let \(c^\parallel\) be a heaviest vertex in \(I^\parallel\). Let \(C^\downarrow = \{v \in (C_U^C \setminus \{c\}) : w(I^C_C \setminus \{c\}) \geq \frac{w(I^C_C \setminus \{c\})}{4}\}\) be the set of vertices in \(C_U^C \setminus \{c\}\) which have a “heavy” non-neighbourhood in \(I^C_C\), and let \(c^\downarrow\) be a heaviest vertex in \(C^\downarrow\). Let \(C^\downarrow = \{v \in (C_U^C \setminus \{c\}) : w(N(v) \cap (C_U^C \setminus \{c\})) \geq \frac{w(C_U^C \setminus \{c\})}{4}\}\) be the set of vertices in \(C_U^C \setminus \{c\}\) which have a “heavy” neighbourhood in \(C_U^C \setminus \{c\}\).

Then at least one of the following statements is true.

(a) Picking a vertex proportionately at random from the set \(X \cup (C_X \setminus I^C_C)\) yields a vertex \(v \in C^\parallel\) with probability at least \(1/(20(1 + \frac{12}{\varepsilon}))\), or
Picking a vertex proportionately at random from the set $X \cup (C_X \setminus I_U^*)$ yields a vertex $v \in C^1$ with probability at least $1/(4(1 + \frac{12}{5}))$.  

(2) Picking a vertex proportionately at random from the set $X \cup (I_X \setminus C_U^*)$ yields a vertex $v \in I^\parallel$ with probability at least $1/(20(1 + \frac{12}{5}))$, or

(2b) Picking a vertex proportionately at random from the set $X \cup (I_X \setminus C_U^*)$ yields a vertex $v \in I^\parallel$ with probability at least $1/(4(1 + \frac{12}{5}))$.

Proof. We structure the proof as a number of short claims.

\[ \triangleright \text{Claim 24.1.} \quad w(X \cup (C_X \setminus I_U^*)) < 4(1 + \frac{12}{5}) \cdot w(C^\parallel) \]

Proof. Since $(I_U^*, C_U^*)$ is a light pair we get from Lemma 4 that $w(C^\parallel) > \frac{w(C_U^*)}{4}$ holds. Since $(G, w, (C, I, U))$ is a hard instance we get from Lemma 22 that $w(X \cup (C_X \setminus I_U^*)) < (1 + \frac{12}{5}) \cdot w(C_U^*)$ holds. Putting these together we get the claim. \(\triangleright\)

\[ \triangleright \text{Claim 24.2.} \quad \text{If } w(c^\parallel) < \frac{4w(C^\parallel)}{5} \text{ holds then part (1a) of the lemma holds.} \]

Proof. If $C^\parallel \subseteq X \cup (C_X \setminus I_U^*)$ holds then from Claim 24.1 we get that part (1a) of the lemma holds.

So suppose $C^\parallel \notin X \cup (C_X \setminus I_U^*)$ holds. Then we get from Observation 15 that $|C^\parallel \setminus (X \cup (C_X \setminus I_U^*))| = 1$ holds. Since a heaviest vertex in $C^\parallel$ has weight less than $\frac{4w(C^\parallel)}{5}$ we get that $w(C^\parallel \setminus (X \cup (C_X \setminus I_U^*))) < \frac{2w(C^\parallel)}{5}$ holds as well. Hence $w(C^\parallel \cap (X \cup (C_X \setminus I_U^*))) > \frac{w(C^\parallel)}{5}$ holds, and using Claim 24.1 we get that picking a vertex proportionately at random from the set $X \cup (C_X \setminus I_U^*)$ yields a vertex from the set $C^\parallel \cap (X \cup (C_X \setminus I_U^*))$ with probability more than $1/20(1 + \frac{12}{5})$, which satisfies part (1a) of the lemma. \(\triangleright\)

From now on we assume that $w(c^\parallel) \geq \frac{4w(C^\parallel)}{5}$ holds. If $c^\parallel \in X \cup (C_X \setminus I_U^*)$ holds, then from Claim 24.1 and our assumption about $w(c^\parallel)$ we get that picking a vertex proportionately at random from the set $X \cup (C_X \setminus I_U^*)$ yields the vertex $c^\parallel$ itself with probability at least $1/5(1 + \frac{12}{5})$, which satisfies part (1a) of the lemma. So from now on we assume that $c^\parallel \notin X \cup (C_X \setminus I_U^*)$ holds.

\[ \triangleright \text{Claim 24.3.} \quad \text{If } ((C_U^* \setminus \{c^\parallel\}), I_U^*) \text{ is a light pair then part (1a) of the lemma holds.} \]

Proof. Since $((C_U^* \setminus \{c^\parallel\}), I_U^*)$ is a light pair we get from Lemma 4 that $w(C^\parallel \cap (C_U^* \setminus \{c^\parallel\})) > \frac{w((C_U^* \setminus \{c^\parallel\}))}{4}$ holds. It follows that if we pick a vertex from the set $C_U^* \setminus \{c^\parallel\}$ proportionately at random with probability $p$ then we get a vertex from the set $C^\parallel$ with probability more than $\frac{p}{4}$.

Since $c^\parallel \notin X \cup (C_X \setminus I_U^*)$ holds, from Observation 15 we get that $(C_U^* \setminus \{c^\parallel\}) \subseteq X \cup (C_X \setminus I_U^*)$ holds. Observe that, in general, $(C_X \setminus I_U^*) \subseteq (C_U^* \cup U_{OPT})$ holds. In this case since the vertex $c^\parallel \in C_U^*$ is not in the set $C_X \setminus I_U^*$ we get that $(C_X \setminus I_U^* \subseteq ((C_U^* \setminus \{c^\parallel\}) \cup U_{OPT})$ holds. Hence we get that $w(X \cup (C_X \setminus I_U^*)) \leq w(X) + w(C_U^* \setminus \{c^\parallel\}) + w(U_{OPT}) \leq 6w(OPT) + w(C_U^* \setminus \{c^\parallel\})$ holds in this case. Also, since $(G, w, (C, I, U))$ is a hard instance we get—Definition 20—that $w(C_U^* \setminus \{c^\parallel\}) > \frac{c \cdot w(OPT)}{2}$ holds. Putting these together we get

\[
\frac{w(X \cup (C_X \setminus I_U^*))}{w(C_U^* \setminus \{c^\parallel\})} \leq \frac{6w(OPT) + w(C_U^* \setminus \{c^\parallel\})}{w(C_U^* \setminus \{c^\parallel\})} = 1 + \frac{6w(OPT)}{w(C_U^* \setminus \{c^\parallel\})} < 1 + \frac{6w(OPT)}{c \cdot w(OPT)} = \frac{\varepsilon + 12}{\varepsilon}.
\]
Thus we get that $w(X \cup (C_X \setminus I_U^*)) < (1 + \frac{12}{5})w(C_U^* \setminus \{c^3\})$ holds. It follows that picking a vertex proportionately at random from the set $X \cup (C_X \setminus I_U^*)$ yields a vertex from the set $C_U^* \setminus \{c^3\}$ with probability more than $1/(1 + \frac{12}{5})$. And this vertex is in the set $C_U^*$ with probability more than $1/4(1 + \frac{12}{5})$, which satisfies part (1a) of the lemma.

From now on we assume that $((C_U^* \setminus \{c^3\}), I_U^*)$ is a heavy pair.

\[ \text{Claim 24.4.} \quad w(X \cup (I_X \setminus C_U^*)) < 4(1 + \frac{12}{5}) \cdot w(I_U^*) \]

\[ \text{Proof.} \quad \text{Since } ((C_U^* \setminus \{c^3\}), I_U^*) \text{ is a heavy pair we get from Lemma 4 that } w(I_U^*) > \frac{w(I_U^*)}{4} \text{ holds.} \]

Since $(G, w, (C, I, U))$ is a hard instance we get from Lemma 22 that $w(X \cup (I_X \setminus C_U^*)) < \frac{w(I_U^*)}{4} \cdot w(I_U^*)$ holds. Putting these together we get the claim.

\[ \text{Claim 24.5.} \quad \text{If } w(\{i\}) < \frac{4w(I_U^*)}{5} \text{ holds then part (2a) of the lemma holds.} \]

\[ \text{Proof.} \quad \text{If } I_U^* \subseteq X \cup (I_X \setminus C_U^*) \text{ holds then from Claim 24.4 we get that part (2a) of the lemma holds.} \]

So suppose $I_U^* \not\subseteq X \cup (I_X \setminus C_U^*)$ holds. Then we get from Observation 15 that $|I_U^* \setminus (X \cup (I_X \setminus C_U^*))| = 1$ holds. Since a heaviest vertex in $I_U^*$ has weight less than $\frac{w(I_U^*)}{4}$ we get that $w(I_U^* \setminus (X \cup (I_X \setminus C_U^*)) < \frac{4w(I_U^*)}{5}$ holds as well. Hence $w(I_U^* \cap (X \cup (I_X \setminus C_U^*)) > \frac{w(I_U^*)}{5}$ holds, and using Claim 24.4 we get that picking a vertex proportionately at random from the set $X \cup (I_X \setminus C_U^*)$ yields a vertex from the set $I_U^* \cap (X \cup (I_X \setminus C_U^*))$ with probability more than $1/20(1 + \frac{12}{5})$, which satisfies part (2a) of the lemma.

From now on we assume that $w(\{i\}) \geq \frac{4w(I_U^*)}{5}$ holds. If $\{i\} \in X \cup (I_X \setminus C_U^*)$ holds then from Claim 24.4 and our assumption about $w(\{i\})$ we get that picking a vertex proportionately at random from the set $X \cup (I_X \setminus C_U^*)$ yields the vertex $\{i\}$ itself with probability at least $1/5(1 + \frac{12}{5})$, which satisfies part (2a) of the lemma. So from now on we assume that $\{i\} \notin X \cup (I_X \setminus C_U^*)$ holds.

\[ \text{Claim 24.6.} \quad \text{If } ((C_U^* \setminus \{c^3\}), I_U^* \setminus \{i^3\}) \text{ is a light pair then part (1b) of the lemma holds.} \]

\[ \text{Proof.} \quad \text{Since } ((C_U^* \setminus \{c^3\}), (I_U^* \setminus \{i^3\})) \text{ is a light pair we get from Lemma 4 that } w(C_U^* \setminus \{c^3\}) > \frac{w(C_U^* \setminus \{c^3\})}{w((C_U^* \setminus \{c^3\}))} \text{ holds.} \]

It follows that if we pick a vertex from the set $C_U^* \setminus \{c^3\}$ proportionately at random with probability $p$ then we get a vertex from the set $C_U^*$ with probability more than $\frac{p}{4}$. Applying the exact same argument as in the proof of Claim 24.3 we get that picking a vertex proportionately at random from the set $X \cup (C_X \setminus I_U^*)$ yields a vertex from the set $C_U^* \setminus \{c^3\}$ with probability more than $1/(1 + \frac{12}{5})$. And this vertex is in the set $C_U^*$ with probability more than $1/4(1 + \frac{12}{5})$, which satisfies part (1b) of the lemma.

From Lemma 4 we get that in the remaining case $((C_U^* \setminus \{c^3\}), I_U^* \setminus \{i^3\})$ is a heavy pair.

\[ \text{Claim 24.7.} \quad \text{If } ((C_U^* \setminus \{c^3\}), I_U^* \setminus \{i^3\}) \text{ is a heavy pair then part (2b) of the lemma holds.} \]

\[ \text{Proof.} \quad \text{Since } ((C_U^* \setminus \{c^3\}), (I_U^* \setminus \{i^3\})) \text{ is a heavy pair we get from Lemma 4 that } w(I_U^* \setminus \{i^3\}) > \frac{w(I_U^* \setminus \{i^3\})}{4} \text{ holds.} \]

It follows that if we pick a vertex from the set $I_U^* \setminus \{i^3\}$ proportionately at random with probability $p$ then we get a vertex from the set $I_U^*$ with probability more than $\frac{p}{4}$. Since $\{i^3\} \not\in X \cup (I_X \setminus C_U^*)$ holds, from Observation 15 we get that $(I_U^* \setminus \{i^3\}) \subseteq X \cup (I_X \setminus C_U^*)$ holds. Observe that, in general, $(I_X \setminus C_U^*) \subseteq (I_U^* \cup U_{OPT})$ holds. In this case since the vertex $\{i^3\} \in I_U^*$ is not in the set $I_X \setminus C_U^*$ we get that $(I_X \setminus C_U^*) \subseteq ((I_U^* \setminus \{i^3\}) \cup U_{OPT})$. Hence
we get that \(w(\mathcal{X} \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*) \leq w(\mathcal{X}) + w(I_X^* \setminus \{i^*\}) + w(U_{OPT}) \leq 6w(OPT) + w(I_X^* \setminus \{i^*\}) \)
holds in this case. Also, since \((\mathcal{G}, w, (\mathcal{C}, I, U))\) is a hard instance we get—Definition 20—that
\[w(I_X^* \setminus \{i^*\}) > \frac{\varepsilon w(OPT)}{2}\]
holds. Putting these together we get
\[
\frac{w(\mathcal{X} \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*)))}{w(I_X^* \setminus \{i^*\})} \leq \frac{6w(OPT) + w(I_X^* \setminus \{i^*\})}{w(I_X^* \setminus \{i^*\})} = 1 + \frac{6w(OPT)}{w(I_X^* \setminus \{i^*\})} < 1 + \frac{6w(OPT)}{\varepsilon w(OPT)} = \varepsilon + 12.
\]
Thus we get that \(w(\mathcal{X} \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*))) < (1 + \frac{12}{\varepsilon})w(I_X^* \setminus \{i^*\}) \) holds. It follows that picking
a vertex proportionately at random from the set \(\mathcal{X} \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*)\) yields a vertex from the
set \(I_X^* \setminus \{i^*\}\) with probability more than \(1/(1 + \frac{12}{\varepsilon})\). And this vertex is in the set \(I^+\) with
probability more than \(1/4(1 + \frac{12}{\varepsilon})\), which satisfies part (2b) of the lemma. \(\triangleright\)

Thus, assuming \((\mathcal{C}_U^*, I_U^*)\) is a light pair, at least one of the statements is always true. \(\triangleright\)

From Lemma 23 and Lemma 24 we get

\[\triangleleft\text{Lemma 25.} \quad \text{Let } (\mathcal{G}, w, (\mathcal{C}, I, U)) \text{ be a hard instance of A-SVD and let } \varepsilon, OPT, \mathcal{C}^*, \mathcal{I}^*, \mathcal{C}_U^*, \mathcal{I}_U^* \text{ as in Definition 13. Then one of the following statements is true.}\]

\(1\text{a})\) Picking a vertex proportionately at random from \(\mathcal{X} \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*)\) yields a vertex from
\[\{v \in I_U^* | w(N(v) \cap C_U^*) \geq \frac{w(C_U^*)}{4}\} \text{ with probability at least } 1/20(1 + \frac{12}{\varepsilon}).\]

\(1\text{b})\) Picking a vertex proportionately at random from \(\mathcal{X} \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*)\) yields a vertex from
\[\{v \in I_U^* | w(N(v) \cap (C_U^* \setminus \{c^*\}) \geq \frac{w(C_U^*)}{4}\{c^*\}\} \text{ with probability at least } 1/20(1 + \frac{12}{\varepsilon}), \text{ for some vertex } c^* \in C_U^*\].

\(2\text{a})\) Picking a vertex proportionately at random from \(\mathcal{X} \cup (\mathcal{C}_X \setminus \mathcal{I}_U^*)\) yields a vertex from
\[\{v \in C_U^* | w(I_U^* \setminus N(v)) \geq \frac{w(I_U^*)}{4}\} \text{ with probability at least } 1/20(1 + \frac{12}{\varepsilon}).\]

\(2\text{b})\) Picking a vertex proportionately at random from \(\mathcal{X} \cup (\mathcal{C}_X \setminus \mathcal{I}_U^*)\) yields a vertex from
\[\{v \in C_U^* | w((I_U^* \setminus \{i^*\}) \setminus N(v)) \geq \frac{w(I_U^*)}{2}\} \text{ with probability at least } 1/20(1 + \frac{12}{\varepsilon}), \text{ for some vertex } i^* \in I_U^*\].

\textbf{Proof.} From Lemma 4 we get that \((I_U^*, C_U^*)\) is either a heavy pair or a light pair. If \((I_U^*, C_U^*)\)

is a heavy pair then Lemma 23 applies, and at least one of the four options of that lemma
holds. Option (1a) of Lemma 23 implies option (1a) of the current lemma. Option (1b) of
Lemma 23 implies option (1b) of the current lemma. Options (2a) and (2b) of Lemma 23
both imply option (2b) of the current lemma.

If \((I_U^*, C_U^*)\) is a light pair then Lemma 24 applies, and at least one of the four options
of that lemma holds. Option (1a) of Lemma 24 implies option (2a) of the current lemma.
Option (1b) of Lemma 24 implies option (2b) of the current lemma. Options (2a) and (2b)
of Lemma 24 both imply option (1b) of the current lemma.

Thus in every case, one of the four options of the current lemma holds. \(\triangleright\)

\[\triangleleft\text{Lemma 26.} \quad \text{Let } (\mathcal{G}, w, (\mathcal{C}, I, U)) \text{ be a hard instance of A-SVD and let } \varepsilon, OPT, \mathcal{C}^*, \mathcal{I}^*, \mathcal{C}_U^*, \mathcal{I}_U^* \text{ as in Definition 13.}\]

1. There is a randomized polynomial-time algorithm which, given \((\mathcal{G}, w, (\mathcal{C}, I, U))\) as input,
picks a vertex proportionately at random from the set \(\mathcal{X} \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*)\) with probability
at least \(\frac{1}{2}\). That is, the algorithm runs in polynomial time and outputs a vertex \(v\), and
the following hold with probability at least \(\frac{1}{2}\): (i) \(v \in X \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*)\), and (ii) for any
\(x \in (X \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*))\), \(P[v = x] = w(x)/w(X \cup (\mathcal{I}_X \setminus \mathcal{C}_U^*)))\).
2. There is a randomized polynomial-time algorithm which, given \((G, w, (C, I, U))\) as input, picks a vertex proportionately at random from the set \(X \cup (C_X \setminus I_U^*)\) with probability at least \(\frac{1}{2}\). That is, the algorithm runs in polynomial time and outputs a vertex \(v\), and the following hold with probability at least \(\frac{1}{2}\): (i) \(v \in X \cup (C_X \setminus I_U^*)\), and (ii) for any \(x \in (X \cup (C_X \setminus I_U^*))\), \(Pr[v = x] = w(x)/w(X \cup (C_X \setminus I_U^*))\).

**Proof.** Given an instance \((G, w, (C, I, U))\) of Annotated Split Vertex Deletion as input, in each case the algorithm first applies Remark 14 to compute a 5-factor approximate solution \(X\) to the Split Vertex Deletion instance \((G[U], w_U)\), and a split partition \((C_X, I_X)\) of the split graph \(G[U] - X\), in polynomial time.

The two cases are symmetric; we prove each case in turn.

1. In this case the algorithm picks a vertex \(v_1\) proportionately at random from the set \(X \cup I_X\). It then deletes \(v_1\) from \(X \cup I_X\) and picks a vertex \(v_2\) proportionately at random from the remaining set \((X \cup I_X) \setminus \{v_1\}\). Finally, it returns one of the two vertices \(\{v_1, v_2\}\) uniformly at random as the vertex \(v\).

This procedure clearly runs in polynomial time. We now analyze the probability of success. Suppose \(I_X \cap C_U^* = \emptyset\) holds. Then \(X \cup I_X = X \cup (I_X \setminus C_U^*)\) holds, and vertex \(v_1\) satisfies the requirement on vertex \(v\) with probability 1. Since the algorithm returns vertex \(v_1\) with probability \(\frac{1}{2}\), in this case the algorithm succeeds with probability \(\frac{1}{2}\).

The other case is when \(I_X \cap C_U^* \neq \emptyset\). Now, since \(I_X\) is an independent set and \(C_U^*\) a clique, we get that \(|I_X \cap C_U^*| = 1\) holds in this case. So let \(I_X \cap C_U^* = \{y\}\), and hence \(X \cup (I_X \setminus C_U^*) = (X \cup I_X) \setminus \{y\}\). Note that we sample two distinct vertices \(v_1\) and \(v_2\) from \(X \cup I_X\), and then set \(v\) as one of them uniformly at random. Now consider two cases:

a. Suppose that \(v_1 = y\). Then we sample \(v_2\) from \((X \cup I_X) \setminus \{y\} = X \cup (I_X \setminus C_U^*)\) proportionately at random. Then we pick \(v \in \{v_1, v_2\}\) uniformly at random. Hence, with probability \(\frac{1}{2}\) we return \(v_2\), which satisfies all the required conditions.

b. Otherwise, \(v_1 \neq y\). Then conditioned on this event (when we pick \(v_1\)), the following holds: for any \(x \in X \cup (I_X \setminus C_U^*) = (X \cup I_X) \setminus \{y\}\), \(Pr[v_1 = x] = w(x)/w(X \cup (I_X \setminus C_U^*))\).

Once again, with probability \(\frac{1}{2}\) we return \(v_1\), and it satisfies all the required conditions.

2. In this case the algorithm picks a vertex \(v_1\) proportionately at random from the set \(X \cup C_X\). It then deletes \(v_1\) from \(X \cup C_X\) and picks a vertex \(v_2\) proportionately at random from the remaining set \((X \cup C_X) \setminus \{v_1\}\). Finally, it returns one of the two vertices \(\{v_1, v_2\}\) uniformly at random as the vertex \(v\).

This procedure clearly runs in polynomial time. We now analyze the probability of success. Suppose \(C_X \cap I_U^* = \emptyset\) holds. Then \(X \cup C_X = X \cup (C_X \setminus I_U^*)\) holds, and vertex \(v_1\) satisfies the requirement on vertex \(v\) with probability 1. Since the algorithm returns vertex \(v_1\) with probability \(\frac{1}{2}\), in this case the algorithm succeeds with probability \(\frac{1}{2}\).

The other case is when \(C_X \cap I_U^* \neq \emptyset\). Then \(|C_X \cap I_U^*| = 1\) and let \(C_X \cap I_U^* = \{y\}\). Note that we sample two distinct vertices \(v_1\) and \(v_2\) from \(X \cup C_X\), and then set \(v\) as one of them uniformly at random. Now consider two cases:

a. Suppose that \(v_1 = y\). In this case, we sample \(v_2\) from \(X \cup C_X \setminus \{y\}\) proportionately at random. The algorithm returns \(v_2\) with probability at least \(\frac{1}{2}\), which satisfies all the required conditions.

b. Otherwise \(v_1 \neq y\). Then conditioned on this event (when we pick \(v_1\)), the following holds: for any \(x \in (X \cup C_X) \setminus \{y\} = X \cup (C_X \setminus I_U^*)\), \(Pr[v_1 = x] = w(x)/w(X \cup (C_X \setminus I_U^*))\).

The algorithm returns \(v_1\) with probability at least \(\frac{1}{2}\), which satisfies all the required conditions.
Algorithm 1

Input: An instance \((G, w, (C, I, U))\) of A-SVD, a tuples \((\beta_C^1, \beta_C^2, \beta_I^1, \beta_I^2)\) and \(\varepsilon > 0\).
Output: A \((2 + \varepsilon)\)-factor approximate solution to \((G, w, (C, I, U))\).

1. procedure ASVD-APPROX((\(G, w, (C, I, U)\)), \(\varepsilon, \beta_C^1, \beta_C^2, \beta_I^1, \beta_I^2\))
2. if \(U = \emptyset\) then

31. return \(S\)
32. end procedure

3.1 Polynomially Bounded Weights

Let us first consider instances \((G, w)\) of SVD which have polynomially bounded weights. Let \(n = |V(G)|\). Recall that \(w(v) \geq 1\) holds for each vertex \(v\) of \(G\). We say that the weight function \(w\) is polynomially bounded if, in addition, \(\sum_{v \in V(G)} w(v) \leq c_1 n^\omega\) holds for every \(v \in V(G)\) and some constants \(c_0, c_1\). For such instances we have the following theorem.

**Theorem 27.** There exists a randomized algorithm that given a graph \(G\), a polynomially bounded weight function \(w\) on \(V(G)\) and \(\varepsilon > 0\), runs in time \(O(n^{f(\varepsilon)})\) and outputs \(S \subseteq V(G)\) such that \(G - S\) is a split graph and \(w(S) \leq (2 + \varepsilon)w(OPT)\) with probability at least \(1/2\).
where $OPT$ is a minimum weight split vertex deletion set of $G$. Here, $f(\varepsilon) = 6 + \log(80(1 + 12/\varepsilon)) - 4c_0 \log(c_1)/\log(4/3)$, where $c_0, c_1$ are constants such that $w(V) \leq c_1 \cdot n^{c_0}$.

**Proof.** Let us fix an optimum solution $OPT$ to $(G, w)$. We treat the instance $(G, w, (C = \emptyset, I = \emptyset, U = V(G)))$ of A-SVD, and apply Algorithm 1 to it, along with the given value of $\varepsilon$ and four integers $\beta_1^C, \beta_2^C, \beta_1^I, \beta_2^I$ each set to $[\log_{4/3}(w(V(G)))]$. Note that, as $w$ is polynomially-bounded, we have $w(V(G)) \leq c_1 n^{c_0}$ for some constants $c_0, c_1$, and hence $\beta' \leq c_2 \log(n)$ for every $\beta' \in \{\beta_1^C, \beta_2^C, \beta_1^I, \beta_2^I\}$ where $c_2$ is a constant. We will show that the value $\beta = 1 + \beta_1^C + \beta_2^C + \beta_1^I + \beta_2^I \leq 1 + 4c_2 \log(n)$ is an upper-bound on the depth of the recursion tree of Algorithm 1, and that in each recursive call this value drops by 1. Hence the depth of recursion is bounded by $\beta$. Each recursive call is made on more constrained sub-instances of A-SVD where the underlying graph $G$, weight function $w$, and the value of $\varepsilon$ remain fixed. When one of $\{\beta_1^C, \beta_2^C, \beta_1^I, \beta_2^I\}$ falls to $-1$, we argue that the current instance must be an easy instance (see Definition 20), assuming all the recursive calls leading the current call were “good” (as defined below). During its run the algorithm also computes a 5-approximate solution $X$ to $(G[U], w)$ using Theorem 6; let $I_X, C_X$ be a fixed split partition of $G[U] - X$. We have a split partition $(C^*, I^*)$ of $G - OPT$ and we define $I'_U = I^* \cap U, C'_U = C^* \cap U$. These sets, introduced in Definition 13, play an important role in Algorithm 1 and its analysis.

To argue the correctness of Algorithm 1, we require the following definition. An invocation ASVD-APPROX$(G, w, (C, I, U), \varepsilon, \beta_1^C, \beta_2^C, \beta_1^I, \beta_2^I)$ is good if the following conditions are true:

- $\beta_1^C \geq \log_{4/3}(w(C_U^*))$,
- $\beta_2^C \geq \log_{4/3}(w(C_U^* \setminus \{c\}))$ for some $c \in C_U^*$,
- $\beta_1^I \geq \log_{4/3}(w(I_U^*))$, and
- $\beta_2^I \geq \log_{4/3}(w(I_U^* \setminus \{i\}))$ for some $i \in I_U^*$.

Note that the definitions of $C_U^*$ and $I_U^*$ depend only on $(G, w, (C, I, U))$ and on the optimum solution $OPT$ that was fixed at the beginning. These sets are hypothetical and unknown, and we can’t directly test if an invocation of Algorithm 1 is a good invocation. However, observe that in the initial call, $U = V(G)$ and we set each of $\beta_1^C, \beta_2^C, \beta_1^I, \beta_2^I$ to $[\log_{4/3}(w(V(G)))]$, and hence the initial invocation is good. We will argue that if the current invocation is good and the instance of A-SVD is a hard instance (see Definition 20), then each recursive call made by the algorithm is good with a constant probability (which depends on $\varepsilon$). Then (via an induction) we argue that a good recursive call will return a $(2 + \varepsilon)$-approximate solution with probability at least $1/2$, and hence with constant probability we obtain a $(2 + \varepsilon)$-approximate solution from a recursive call. To boost the probability of success to $1/2$, we need to repeat this process constantly many times, so we make constantly many recursive calls. Finally, to bound the running time, we argue that the depth of the recursion tree is bounded by $\beta = O(\log n)$, and we make constantly many recursive calls in each invocation of the algorithm. So the total number of calls made to this algorithm, which is upper-bounded by the size of the recursion tree, is $n^{O(1)}$. This means that in polynomial time, with probability at least $1/2$, we obtain a $(2 + \varepsilon)$-approximate solution to $(G, w)$. Let us now present these arguments formally.

Let us recall the optimum solution $OPT$ to $(G, w)$ that was fixed at the beginning. We say that an instance $(G, w, (C, U, I))$ is a nice instance if the solution $OPT$ is also an optimum solution to this A-SVD instance. This means that a split partition $C^*, I^*$ of $G - OPT$ satisfies, $C^* \cap I = \emptyset$ and $I^* \cap C = \emptyset$. Note that this condition is trivially satisfied at the beginning for the starting instance $(G, w, (C = \emptyset, I = \emptyset, U = V(G)))$. Let us consider an invocation of Algorithm 1 on a nice instance of $(G, w, (C, I, U))$ with polynomially bounded weight.
function $w$ and $\beta_1^C, \beta_1^S, \beta_1^I, \beta_1^U$ such that it is a good invocation. Let $S$ denote the solution returned by it. We will show that $S$ is a $(2 + \varepsilon)$-approximate solution with probability at least $\frac{1}{2}$, by an induction on $|U|$. Suppose that $|U| = 0$, i.e. $U = \emptyset$. Then Lemma 12 ensures that $S$ is a 2-approximation solution. This forms the base case of our induction on $|U|$.

Now suppose that $|U| > 0$, and we have two cases depending on whether $(G, w, (C, I, U))$ is an easy instance or not. If it is an easy instance, then either the premise of Lemma 16 or the premise of Lemma 18 holds. Hence, one of $S_1, S_2, S_3$ is a $(2 + \varepsilon)$-approximation to $(G, w, (C, I, U))$. Moreover, we claim that if any one of $\beta_1^C, \beta_1^S, \beta_1^I, \beta_1^U$ drops to $-1$, then the instance $(G, w, (C, I, U))$ is an easy instance. Consider the case when $\beta_1^C = -1$. Then $\log_{4/3}(w(C_U^* \setminus \{c\})) = -1$ for some $c \in C_U^*$. This means $w(C_U^* \setminus \{c\}) < 3/4$, and since $w(v) \geq 1$ for every $v \in V(G)$, it must be the case that $C_U^* = \{c\}$. Hence, the premise of Lemma 18 holds and we obtain a $(2 + \varepsilon)$-approximate solution for $(G, w, (C, I, U))$. Similar arguments apply to the other cases, i.e. when $\beta_1^I = -1$, or $\beta_1^S = -1$ or $\beta_1^U = -1$, and we can obtain a $(2 + \varepsilon)$-approximation in all these cases. Therefore, in all these cases $S$ is a $(2 + \varepsilon)$-approximation to $(G, w, (C, I, U))$.

Now, consider the case when the given instance is a hard instance, i.e. $U \neq \emptyset$ and the premises of Lemma 16 and Lemma 18 don’t hold. In this case $\beta_1^C, \beta_1^S, \beta_1^I, \beta_1^U \geq 0$. Recall that $X$ is a 5-approximate solution to $\text{SVD}$ in the subgraph $G[U]$, and hence $w(X) \leq 5 \cdot \text{OPT}$. We will make recursive calls on instances of $\text{A-SVD}$ of the form $(G, w, (C', I', U'))$ such that $C \subseteq C', I \subseteq I'$ and $U' \subseteq U$. Suppose that $(G, w, (C', I', U'))$ is a nice instance. Then by the induction hypothesis, as $|U'| < |U|$, we can assume that Algorithm 1 returns a $(2 + \varepsilon)$-approximate solution $\hat{S}$ to this instance with probability at least $1/2$. This is an approximate solution to the current instance as well:

\[ \triangleright \text{Claim 27.1. } \hat{S} \text{ is a } (2 + \varepsilon)-\text{approximate solution to } (G, w, (C, I, U)) \]

\textbf{Proof.} Observe that, since $\hat{S}$ is feasible solution to the nice instance $(G, w, (C', I', U'))$, there is a split partition $(C_{\hat{S}}, I_{\hat{S}})$ of $G - \hat{S}$ such that $C' \cap I_{\hat{S}} = \emptyset$ and $I' \cap C_{\hat{S}} = \emptyset$. Therefore, we have $C \cap I_{\hat{S}} = \emptyset$ and $I \cap C_{\hat{S}} = \emptyset$, i.e. $\hat{S}$ is a feasible solution to $(G, w, (C, I, U))$. Since $w(\hat{S}) \leq (2 + \varepsilon)w(\text{OPT})$, the claim is true. \hfill \blacktriangle

Let us now consider the recursive calls made by the algorithm for each $j \in \{1, 2, \ldots, b(\varepsilon) = \lceil 80(1 + \frac{12}{e^2}) \rceil \}$, and argue that with a constant probability (depending on $\varepsilon$) we can obtain a $(2 + \varepsilon)$-approximation to the given instance. In each recursive call, one of $\beta_1^C, \beta_1^S, \beta_1^I, \beta_1^U$ drops by exactly 1. Let us fix $j \in \{1, 2, \ldots, b(\varepsilon) \}$ and consider the two vertices $v_I, v_C$ sampled using Lemma 26. Since $(G, w, (C, I, U))$ is a hard instance, the following hold.

- With probability at least $1/2$, $v_I \in X \cup (I_X \setminus C_U^*)$, and for any $x \in (X \cup (I_X \setminus C_U^*))$, $Pr[v_I = x] = \frac{w(x)}{w(X \cup (I_X \setminus C_U^*))}$.
- With probability at least $1/2$, $v_C \in X \cup (C_X \setminus I_U^*)$, and for any $x \in (X \cup (C_X \setminus I_U^*))$, $Pr[v_C = x] = \frac{w(x)}{w(X \cup (C_X \setminus I_U^*))}$.

By the induction hypothesis, any good invocation $\text{ASVD-APPROX}(G, w, (C', I', U'), \varepsilon, \beta_1^C, \beta_1^S, \beta_1^I, \beta_1^U)$ where $(G, w, (C', I', U'))$ is a nice instance and $|U'| < |U|$ holds, returns a $(2 + \varepsilon)$-approximate solution to $(G, w, (C', I', U'))$ with probability at least $\frac{1}{2}$. We now have four cases, depending on which of the four statements in Lemma 25 is true for $(G, w, (C, I, U))$. In each case we will argue that with constant probability, we make a good recursive call on a nice instance and obtain a $(2 + \varepsilon)$-approximate solution from it.

(i) Suppose that statement (1a) of Lemma 25 is true. That is, picking a vertex proportionally at random from $X \cup (I_X \setminus C_U^*)$ yields a vertex from $\{v \in I_Y^* \mid w(N(v) \cap C_U^*) \geq \frac{w(C_U^*)}{2} \}$ with probability at least $1/20(1 + \frac{12}{e^2})$. Then $v_I \in \{v \in I_Y^* \mid w(N(v) \cap C_U^*) \geq \frac{w(C_U^*)}{4} \}$
with probability at least $1/40(1 + \frac{\epsilon}{2})$. As $v_I \in I^*_U$, every vertex in $Z_C = N(v_I) \cap U$ must either be in $OPT_U$ or in $C^*_U$. Furthermore, $w(Z_C \cap C^*_U) \geq \frac{w(C^*_U)}{4}$. Let $U' = U \setminus Z_C, C' = C \cup Z_C$ and consider the invocation ASVD-APPROX$(G, w, (C', I, U'), \epsilon, \beta_1^C, \beta_2^C)$. Let us argue that it is a good invocation. By definition $C_{U'} = C^* \cap U'$ satisfies $w(C_{U'}) \leq \frac{3}{4} w(C_U)$. Therefore, as $\beta_1^C \geq \log_{4/3}(w(C_U))$, we have $\beta_1^{C_U} - 1 \geq \log_{4/3}(w(C_{U'}))$. Furthermore, observe that $\beta_2^C \geq \log_{4/3}(w(C_U \setminus \{c^*\}))$, and $I, \beta_1^C, \beta_2^C$ remain unchanged. Hence, assuming that the current invocation is good, this invocation is also good. Let us argue that $(G, w, (C', I, U'))$ is a nice instance, i.e. $OPT$ is an optimum solution to it. Towards this, recall that $C' = C \cup Z_C$ where $Z_C = N(v_I) \cup U$ and $v_I \in I^*_U \subseteq I^*$. Hence, every vertex in $Z_C$ is either in $OPT$ or in $C^*$, i.e. $Z_C \cap I^* = \emptyset$. Since $OPT$ is feasible for $(G, w, (C, I, U'))$ we have that $C \cap I^* = \emptyset$. Therefore, $C^* \cap I^* = (C \cup Z_C) \cap I^* = \emptyset$, and hence $OPT$ is a feasible solution for $(G, w, (C', I, U'))$. Finally, as any feasible solution for $(G, w, (C', I, U'))$ is also feasible for $(G, w, (C^*, I, U'))$, and this event happens with probability at least $1/2$. By Claim 27.1, $S_{U'}^{C_U}$ is a $(2 + \epsilon)$-approximate solution to $(G, w, (C, I, U))$. Hence, we obtain a solution $S_{U'}^{C_U}$ that is a $(2 + \epsilon)$-approximation to $(G, w, (C, I, U))$, and this event happens with probability at least $1/80(1 + \frac{12}{\epsilon})$. Note that $\beta_1^C$ drops by 1 in the recursive call.

(ii) Suppose that statement (ib) of Lemma 25 is true. That is, picking a vertex proportionately at random from $X \cup (I_X \setminus C^*_U)$ yields a vertex from $\{v \in I^*_U \setminus w(N(v) \cap (C_U^* \setminus \{c^*\})) \geq \frac{w(G_U \setminus \{c^*\})}{4} \}$ with probability at least $1/20(1 + \frac{\epsilon}{2})$, for some vertex $c^* \in C^*_U$ (as determined by Lemma 25). Then, with probability at least $1/40(1 + \frac{\epsilon}{2})$, $v_I \in \{v \in I^*_U \mid w(N(v) \cap (C_U^* \setminus \{c^*\})) \geq \frac{w(G_U \setminus \{c^*\})}{4} \}$. As $v_I \in I^*_U$, every vertex in $Z_C = N(v_I) \cap U$ must either be in $OPT_U$ or in $C^*_U$. Let $C' = C \cup Z_C, U' = U \setminus Z_C$ and consider the invocation ASVD-APPROX$(G, w, (C', I, U'), \epsilon, \beta_1^C, \beta_2^C)$. Let us argue that it is a good invocation. Let $C = (C^*_U \setminus \{c^*\}) \cap N(v_I)$ and $C_{U'}^* = C^* \cap U'$, and note that either $C_U = \hat{C}$ or $C_U = \hat{C} \cup \{c^*\}$. Since $w(\hat{C}) \leq \frac{3}{4} w(C_U \setminus \{c^*\})$ by the choice of $v_I$, we have $\log_{4/3}(w(\hat{C})) \leq \log_{4/3}(w(C_U \setminus \{c^*\})) \leq 1 - \beta_2^C$. Therefore, if $C_{U'}^* = \hat{C}$, then for any arbitrary $c^* \in C^*_U$, we have $\beta_2^C - 1 \geq \log_{4/3}(w(C_{U'}^* \setminus \{c^*\}))$; otherwise $C_{U'}^* = \hat{C} \cup \{c^*\}$, and $\beta_2^C - 1 \geq \log_{4/3}(w(C_{U'}^* \setminus \{c^*\}))$. Furthermore, observe that $\beta_2^C$ is unchanged and $C_{U'} \subseteq C_{U'}^*$, we have $\log_{4/3}(w(C_{U'}^* \setminus \{c^*\})) \leq \beta_2^C$. Similarly, $I, \beta_1^C, \beta_2^C$ are also unchanged. Hence, this invocation is good. Next, as in the previous case, we can argue that $(G, w, (C', I, U'))$ is a nice instance. Then, as $|U'| < |U|$, by the induction hypothesis the invocation returns a $(2 + \epsilon)$-approximate solution $S_{U'}^{C_U}$ to $(G, w, (C', I, U'))$ with probability at least $1/2$. By Claim 27.1, $S_{U'}^{C_U}$ is a $(2 + \epsilon)$-approximate solution to $(G, w, (C, I, U))$, and this event happens with probability at least $1/80(1 + \frac{12}{\epsilon})$. Note that $\beta_2^C$ drops by 1 in recursive call made here.

(iii) Suppose that statement (2a) of Lemma 25 is true. This case is symmetric to Case-(i), above, where the arguments are made with respect to $v_C \in X \cup (C_X \setminus I^*_U)$. Here $v_C \in \{v \in C^*_U \mid w(I^*_U \cap N(v)) \geq \frac{w(I^*_U)}{4} \} \setminus \{v \mid w(N(v) \cap (C_U^* \setminus \{c^*\})) \geq \frac{w(G_U \setminus \{c^*\})}{4} \}$ with probability at least $1/40(1 + \frac{\epsilon}{2})$. We consider the instance $(G, w, (C, I', U'))$ where $I' = I \cup Z_I, U' = U \setminus Z_I \subseteq U \setminus N(v_C)$. We can argue that this invocation is good and the instance $(G, w, (C, I', U'))$ is nice. Then, as $|U'| < |U|$, by the induction hypothesis, this invocation returns a $(2 + \epsilon)$-approximate solution to $(G, w, (C, I', U'))$ with probability at least $1/2$. Let $S_{I'}^{C_{U'}}$ denote this solution, and we argue that it is also a $(2 + \epsilon)$-approximate solution to $(G, w, (C, I, U))$. In conclusion, we obtain a solution $S_{I'}^{C_{U'}}$ that is a $(2 + \epsilon)$-approximation to $(G, w, (C, I, U))$, and this event happens with probability at least $1/80(1 + \frac{12}{\epsilon})$. Note that $\beta_1^C$ drops by 1
in recursive call made here.

(iv) Suppose that statement (2a) of Lemma 25 is true. This case is symmetric to Case-(ii) above.

Here we have a vertex \( v \in \{ v \in C'_2 \mid w(I'_2 \setminus N(v)) \geq \frac{w(I'_2)}{4} \} \) with probability at least 

\[
1/40(1 + \frac{12}{\gamma}).
\]

We make a recursive call \( \text{ASVD-APPROX}(G, w, (C, I', U'), \epsilon, \beta_1^{C}, \beta_2^{C}, \beta_1^{I}, \beta_2^{I}) \)

where \( I' = I \cup Z_t, U' = U \setminus Z_t \) and \( Z_t = U \setminus N(v_0) \). Here, we obtain a solution 

\( S_{j,2}' \)

that is a \((2 + \epsilon)\)-approximation to \((G, (C, I, U))\), and this event happens with

probability at least \(1/80(1 + \frac{12}{\gamma})\). Note that \( \beta_2^I \) drops by 1 in recursive call made here.

Therefore, if \((G, w, (C, I, U))\) is a hard instance, then for each \( j \in \{1, 2, \ldots, b(\epsilon)\}, (j, j') \) such that \( S_{j,2}' \) is a \((2 + \epsilon)\)-approximate solution to it with probability at least \(1/80(1 + \frac{12}{\gamma})\).

Note that the recursive calls made for any two distinct \( j, j' \in \{1, 2, \ldots, b(\epsilon)\} \) are independent

in each of these calls. Additionally \( U \) drops to a strict subset in each of these calls. Hence in a finite number of steps, either \( U \) becomes empty, or

one of \( \beta_2^C, \beta_2^I, \beta_1^I, \beta_2^I \) becomes equal to \(-1\), and we reach an easy instance. Observe that this
does not happen at some point before the depth of recursion exceeds \( \beta = 1 + 4c_2 \log(n) \).

Hence, the number of recursive calls made for the instance \((G, w)\) is upper bounded by

\[
b(\epsilon) = O(n^{h(\epsilon)})
\]

where \( h(\epsilon) = \log(80(1 + \frac{12}{\gamma})) \cdot 4c_0 \log(c_1) / \log(4/3) \). Recall that \( c_0, c_1 \) are

constants such that \( w(V(G)) \leq c_1 \cdot n^{c_0} \). Observe that in each recursive call, we spend \( O(n^6) \)
time (excluding the recursive calls). Hence the total running time is upper-bounded by \( n^{f(\epsilon)} \)

where \( f(\epsilon) = 6 + \log(80(1 + \frac{12}{\gamma})) \cdot 4c_0 \log(c_1) / \log(4/3) \). Alternatively, this bound on the

running time can be obtained from the Master Theorem.

\[ \Box \]

3.2 General Weight Functions

In this section, we extend Theorem 27 to instances of SVD with general weight function. In

particular we show that given an instance with general weights, we can construct an instance

with polynomially-bounded weights such that an approximate solution to the new instance
can be lifted back to the original instance.

**Lemma 28.** Let \((G, w)\) be an instance of SVD, and \( \epsilon > 0 \) be a constant. Then we can

construct another instance \((G', w')\) of SVD such that \( G' \) is a subgraph of \( G \) and given any \( \alpha \)-approximate solution to \((G', w')\) where \( \alpha \leq 5 \), we can obtain an \((\alpha + \epsilon)\)-approximate solution to \((G, w)\). Moreover, the weight function \( w' \) is polynomially bounded, and \( w'(V(G')) \leq \frac{20n^2}{\epsilon^2} \).

**Proof.** Given the instance \((G, w)\) of SVD, let us compute a 5-approximation \( X \) to it by

applying Theorem 6. Let \( OPT \) denote an optimum solution to \((G, w)\) and note that

\[ w(OPT) = 5w(X) \]

1. Let \( Z = \{ v \in V(G) \mid w(v) \leq \frac{1}{n} \cdot w(X) \} \), and let \( G' = G[V(G) \setminus Z] \).

2. Let \( H = \{ v \in V(G) \mid w(v) > 5w(X) \} \), and define \( w'(v) = w(X) + 1 \) for all other

vertices \( v \in V(G') \setminus H \), define \( w'(v) = w(v) \).

Consider the instance \((G', w'')\), and let \( S \) be an \( \alpha \)-approximate solution to \((G', w'')\). Consider the
solution \( X \subseteq V(G) \) to \((G, w)\) and observe that as \( G' \) is an induced subgraph of \( G \), the graph \( G' - X \) is a split graph. Further, \( w(X) = w''(X) \) (since for any \( v \in X \), \( w(v) \leq w(X) \)) and hence \( w''(v) = w(v) \). Similarly, if we consider the solution \( OPT \) to \((G, w)\), we obtain that \( w''(OPT) = w(OPT) \). Hence, \( w''(OPT') \leq w''(OPT) \) and \( OPT' \cap H = \emptyset \). Therefore, if \( w''(S) \leq \alpha w''(OPT') \) for \( \alpha \leq 5 \), then \( w''(S) \leq \alpha w''(OPT) = \alpha w(OPT) \leq 5w(X) \), and hence \( S \cap H = \emptyset \). Therefore, \( w''(S) = w(S) \) and \( w(S) \leq \alpha w(OPT) \). Then we have the following.

\[
\begin{align*}
w(S \cup Z) &= w(S) + w(Z) \\
&\leq w(S) + n \cdot \varepsilon \cdot \frac{1}{n} \cdot \frac{w(X)}{5} \\
&\leq \alpha w(OPT) + \varepsilon w(OPT)
\end{align*}
\]

Thus given any \( \alpha \)-approximate solution \( S \) to \((G', w'')\) we can construct an \((\alpha + \varepsilon)\)-approximate solution to \((G, w)\). Next, observe that every vertex \( v \in V(G') \) satisfies the following.

\[
\varepsilon \cdot \frac{1}{n} \cdot \frac{w(X)}{5} \leq w''(v) \leq 5w(X) + 1
\]

Define \( w'(v) = w(v) \cdot \frac{1}{\varepsilon} \cdot \frac{5n}{w(X)} \). The we have the following.

\[
1 \leq w'(v) \leq \frac{5w(X) + 1}{w(X)} \cdot \frac{5n}{\varepsilon} \leq \frac{30n}{\varepsilon}
\]

Hence \( w'(v) \geq 1 \) for every vertex \( v \in V(G) \) and \( \sum_{v \in V(G')} w'(v) \leq \frac{30n^2}{\varepsilon} \). Since \( \varepsilon \) is a constant \((G', w')\) is a polynomially-bounded instance. Furthermore, by definition of \( w' \), any \( S \subseteq V(G') \) is an \( \alpha \)-approximate solution to \((G', w')\) if and only if it is an \( \alpha \)-approximate solution to \((G', w'')\). Therefore, if \( \alpha \leq 5 \), then given any \( \alpha \)-approximate solution \( S \) to \((G', w')\), \( S \cup Z \) is an \((\alpha + \varepsilon)\)-approximate solution to \((G, w)\).

We have the following corollary of Theorem 27 and Lemma 28.

**Theorem 29.** There exists a randomized algorithm that given a graph \( G \), a weight function \( w \) on \( V(G) \) and \( \varepsilon > 0 \), runs in time \( O(w^{g(\varepsilon)}) \) and outputs \( S \subseteq V(G) \) such that \( G - S \) is a split graph and \( w(S) \leq 2(1 + \varepsilon)w(OPT) \) with probability at least \( 1/2 \), where \( OPT \) is a minimum weight split vertex deletion set of \( G \). Here, \( g(\varepsilon) = 6 + 8 \log(80(1 + \frac{2}{\varepsilon})) \cdot \log(\frac{30n^2}{\varepsilon}) / \log(4/3) \).

**Proof.** Given the instance \((G, w)\) and \( \varepsilon \), we apply Lemma 28 and obtain an instance \((G', w')\), where \( w'(V(G')) \leq \frac{30n^2}{\varepsilon} \). We then apply Theorem 27 to \((G', w')\) and \( \varepsilon \) and obtain a solution \( S' \) to it. This algorithm runs in time \( |V(G')|^{g(\varepsilon)} \leq n^{g(\varepsilon)} \), where \( g(\varepsilon) = 6 + 8 \log(80(1 + \frac{2}{\varepsilon})) \cdot \log(\frac{30n^2}{\varepsilon}) / \log(4/3) \), and with probability at least \( 1/2 \) \( S' \) is a \((2 + \varepsilon)\)-approximate solution to \((G', w')\). Then by Lemma 28, \( S' \) can be lifted to a \((2(1 + \varepsilon))\)-approximate solution \( S \) to \((G, w)\).

## Conclusion

One of the natural open questions is to obtain a polynomial time \( 2 \)-approximation algorithm for SVD and match the lower bound obtained under UGC. It will be interesting to find other implicit \( d \)-Hitting Set problems and find its correct “approximation complexity”. Towards this we restate the conjecture of Fiorini et al. [6] about a concrete implicit 3-Hitting Set problem: there is a \( 2 \)-approximation algorithm for Cluster Vertex Deletion matching the lower bound under UGC.
