

Additional notes on hash tables

Open Addressing with Linear Probing

**Handout for
F15:Homework:H09**

aka: **Open-Address Hashing, Closed Hashing.** Suppose we are hashing Student objects consisting of name and a two digit perm, using $H(s) = s.perm \% 10$ as our hash function. Here is how the table would evolve after a series of results where we use open hashing with linear probing.

Insert (Alice,34) Insert (Bob, 44) Insert (Chris,29) Insert (Dani, 25) Insert (Erica, 39) Insert (Fred, 72)

More examples

These examples are the type you'd get on a hwk or exam. To save space, we show only the perm numbers, and we show only the FINAL hash table after a sequence of inserts for: (Alex, 3), (Blair, 14), (Chris, 15), (Dakota, 92), (Emory, 65), (Fawn, 35). Note the difference from the different hash functions. As an aside, a quick way to compute the mod of a sequence of numbers is to use Python's lambda function and map feature, as shown at right.

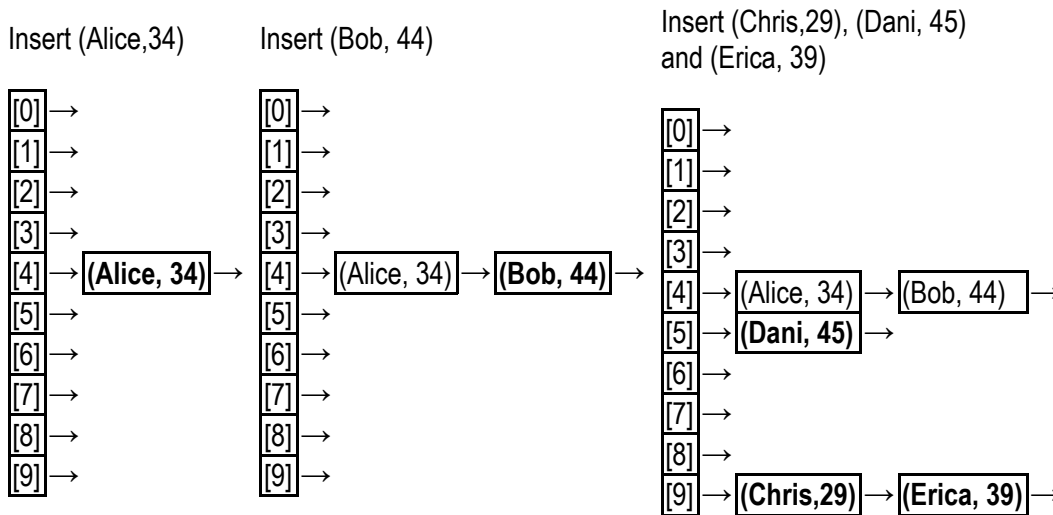

$H(s) = s.perm \% 10$ <table border="1" style="width: 100%; border-collapse: collapse; text-align: center;"> <tr><td>[0]</td><td></td></tr> <tr><td>[1]</td><td></td></tr> <tr><td>[2]</td><td>92</td></tr> <tr><td>[3]</td><td>3</td></tr> <tr><td>[4]</td><td>14</td></tr> <tr><td>[5]</td><td>15</td></tr> <tr><td>[6]</td><td>65</td></tr> <tr><td>[7]</td><td>35</td></tr> <tr><td>[8]</td><td></td></tr> <tr><td>[9]</td><td></td></tr> </table>	[0]		[1]		[2]	92	[3]	3	[4]	14	[5]	15	[6]	65	[7]	35	[8]		[9]		$H(s) = s.perm \% 9$ <table border="1" style="width: 100%; border-collapse: collapse; text-align: center;"> <tr><td>[0]</td><td></td></tr> <tr><td>[1]</td><td></td></tr> <tr><td>[2]</td><td>92</td></tr> <tr><td>[3]</td><td>3</td></tr> <tr><td>[4]</td><td>65</td></tr> <tr><td>[5]</td><td>14</td></tr> <tr><td>[6]</td><td>15</td></tr> <tr><td>[7]</td><td></td></tr> <tr><td>[8]</td><td>35</td></tr> </table>	[0]		[1]		[2]	92	[3]	3	[4]	65	[5]	14	[6]	15	[7]		[8]	35	$H(s) = s.perm \% 11$ <table border="1" style="width: 100%; border-collapse: collapse; text-align: center;"> <tr><td>[0]</td><td></td></tr> <tr><td>[1]</td><td></td></tr> <tr><td>[2]</td><td>35</td></tr> <tr><td>[3]</td><td>3</td></tr> <tr><td>[4]</td><td>14</td></tr> <tr><td>[5]</td><td>15</td></tr> <tr><td>[6]</td><td>92</td></tr> <tr><td>[7]</td><td></td></tr> <tr><td>[8]</td><td></td></tr> <tr><td>[9]</td><td></td></tr> <tr><td>[10]</td><td>65</td></tr> </table>	[0]		[1]		[2]	35	[3]	3	[4]	14	[5]	15	[6]	92	[7]		[8]		[9]		[10]	65	$f(x) = (10*x + x\%2) \% 9$ $H(s) = f(s.perm)$ <table border="1" style="width: 100%; border-collapse: collapse; text-align: center;"> <tr><td>[0]</td><td>35</td></tr> <tr><td>[1]</td><td></td></tr> <tr><td>[2]</td><td>92</td></tr> <tr><td>[3]</td><td>65</td></tr> <tr><td>[4]</td><td>3</td></tr> <tr><td>[5]</td><td>14</td></tr> <tr><td>[6]</td><td></td></tr> <tr><td>[7]</td><td>15</td></tr> <tr><td>[8]</td><td></td></tr> </table>	[0]	35	[1]		[2]	92	[3]	65	[4]	3	[5]	14	[6]		[7]	15	[8]

```

>>> perms=[3,14,15,92,65,35]
>>> map(lambda x:x%10, perms)
[3, 4, 5, 2, 5, 5]
>>> map(lambda x:x%9, perms)
[3, 5, 6, 2, 2, 8]
>>> map(lambda x:x%11, perms)
[3, 3, 4, 4, 10, 2]
>>> def f(x):
...     return ((10*x) + x%2)%9
...
>>> map(f,perms)
[4, 5, 7, 2, 3, 0]
>>>
    
```

Chained Hashing

aka **Separate Chaining, Open Hashing, Hashing with Closed Addressing**. Now suppose we are, as before, hashing Student objects consisting of name and a two digit perm, using $H(s) = s.perm \% 10$ as our hash function—but this time using separate chaining with a linked list at each array element. Here is how the table would evolve after a series of insert operations.

More Separate Chaining examples

These examples are the type you'd get on a hwk or exam. To save space, we show only the perm numbers, and we show only the FINAL hash table after a sequence of inserts for:

(Alex, 3), (Blair, 14), (Chris, 15), (Dakota, 92), (Emory, 65), (Fawn, 35). Note the difference from the different hash functions. As an aside, a quick way to compute the mod of a sequence of numbers is to use Python's lambda function and map feature, as shown at right.

```
>>> perms=[3,14,15,92,65,35]
>>> map(lambda x:x%10, perms)
[3, 4, 5, 2, 5, 5]
>>> map(lambda x:x%9, perms)
[3, 5, 6, 2, 2, 8]
>>> def f(x):
...     return ((10*x) + x%2)%9
...
>>> map(f,perms)
[4, 5, 7, 2, 3, 0]
>>>
```
