CS 293S Parallelism and Dependence Theory

Yufei Ding

Reference Book:
"Optimizing Compilers for Modern Architecture" by Allen \& Kennedy

Slides adapted from Louis-Noël
Pouche, Mary Hall

## End of Moore's Law necessitate parallel computing

End of Moore's law necessitate a means of increasing performance beyond simply producing more complex chips.

One such method is to employ cheaper and less complex chips in parallel architectures

## Amdahl's law

if $f$ is the fraction of the code parallelized, and if the parallelized version runs on a p-processor machine with no communication or parallelization overhead, the speedup is

$$
\frac{1}{(1-f)+(f / p)}
$$

If $f=50 \%$, than the maximum speedup would be ?

## Data locality

Temporal locality occurs when the same data is used several times within a short time period.
Spatial locality occurs when different data elements that are located near to each other are used within a short period of time.

Better locality $\rightarrow$ less cache misses
An important form of spatial locality occurs when all the elements that appear on one cache line are used together.

1. Parallelism and data locality are often correlated.
2. Same/Similar set of Techniques for exploring parallelism and maximizing data locality.

## Data locality

Kernels can often be written in many semantically equivalent ways but with widely varying data localities and performances

$$
\begin{aligned}
& \text { for }(\mathrm{j}=1 ; \mathrm{j}<\mathrm{N} ; \mathrm{j}++) \\
& \quad \text { for }(\mathrm{i}=1 ; \mathrm{i}<\mathrm{N} ; \mathrm{i}++) \\
& \quad A[\mathrm{i}, \mathrm{j}]=0 ;
\end{aligned}
$$

(a) Zeroing an array column-by-column

$$
\begin{gathered}
\text { for }(\mathrm{i}=1 ; \mathrm{i}<\mathrm{N} ; \mathrm{i}++) \\
\text { for }(\mathrm{j}=1 ; \mathrm{j}<\mathrm{N} ; \mathrm{j}++) \\
\quad A[\mathrm{i}, \mathrm{j}]=0 ;
\end{gathered}
$$

(b) Zeroing an array row-by-row.

$$
\begin{aligned}
& \mathrm{b}=\text { ceil }(\mathrm{N} / \mathrm{M}) \\
& \text { for }\left(\mathrm{i}=\mathrm{b} * \mathrm{p} ; \mathrm{i}<\min \left(\mathrm{n}, \mathrm{~b}^{*}(\mathrm{p}+1)\right) ; \mathrm{i}++\right) \\
& \text { for }(\mathrm{j}=1 ; \mathrm{j}<\mathrm{N} ; j++) \\
& \quad A[\mathrm{i}, \mathrm{j}]=0
\end{aligned}
$$

(c) Zeroing an array row-by-row in parallel.

## How to get efficient parallel programs?

Programmer: writing correct and efficient sequential programs is not easy; writing parallel programs that are correct and efficient is even harder.
data locality, data dependence
Debugging is hard

Compiler?
Correctness V.S. Efficiency
Simple assumption
no pointers and pointer arithmetic
Affine: Affine loop + affine array access $+\ldots$

Affine Array Accesses

Common patterns of data accesses: (i, j, k are loop indexes)

$$
\begin{aligned}
& A[i], A[i], A[i-I], A[0], A[i+j], A\left[2 *_{i}\right], A\left[2 *_{i}+I\right], A[i, j], \\
& A[i-I, j+I]
\end{aligned}
$$

Array indexes are affine expressions of surrounding loop indexes

Loop indexes: $i_{n}, i_{n-1}, \ldots, i_{1}$
Integer constants: $c_{n}, c_{n-1}, \ldots, c_{0}$
Array index: $\mathrm{c}_{n} \mathrm{i}_{n}+\mathrm{c}_{\mathrm{n}-1} \mathrm{i}_{n-1}+\ldots+\mathrm{c}_{1} \mathrm{i}_{1}+\mathrm{c}_{0}$
Affine expression: linear expression + a constant term ( $c_{0}$ )

Affine loop

All loop bounds and contained control conditions have to be expressible as a linear affine expression in the containing loop index variables

Affine array accesses

No pointers + no possible aliasing (e.g., overlap of two arrays) between statically distinct base addresses.

## Loop/Array Parallelism

$$
\begin{gathered}
\text { for }(\mathrm{i}=1 ; \mathrm{i}<\mathrm{N} ; \mathrm{i}++) \\
\mathrm{C}[\mathrm{i}]=\mathrm{A}[\mathrm{i}]+\mathrm{B}[\mathrm{i}] ;
\end{gathered}
$$

The loop is parallelizable because each iteration accesses a different set of data.
We can execute the loop on a computer with N processors by giving each processor an unique ID $p=0, I, \ldots, M-I$ and having each processor execute the same code:

$$
\mathrm{C}[\mathrm{p}]=\mathrm{A}[\mathrm{p}]+\mathrm{B}[\mathrm{p}] ;
$$

## Parallelism \& Dependence

for ( $\mathrm{i}=1 ; \mathrm{i}<\mathrm{N} ; \mathrm{i}++$ ) $\mathrm{A}[\mathrm{i}]=\mathrm{A}[\mathrm{i}-1]+\mathrm{B}[\mathrm{i}]$;

$\mathrm{A}[1]=\mathrm{A}[0]+\mathrm{B}[1] ;$ $\mathrm{A}[2]=\mathrm{A}[1]+\mathrm{B}[2] ;$ $\mathrm{A}[3]=\mathrm{A}[2]+\mathrm{B}[3]$;

## Focus of the this lecture

Data Dependence
True, Anti-, Output dependence
Source and Sink
Distance vector, direction vector
Relation between Reordering transformation and Direction vector
Loop dependence
loop-carried dependence
Loop-Independent Dependences
Dependence graph

## Dependence Concepts

Assume statement $\mathrm{S}_{2}$ depends on statement $\mathrm{S}_{1}$.
I. True dependences (RAW hazard): read after write.

Denoted by $\mathrm{S}_{1}$ d $\mathrm{S}_{2}$
2. Antidependence (WAR hazard): write after read.

Denoted by $\mathrm{S}_{1} \mathrm{~d}^{-1} \mathrm{~S}_{2}$
3. Output dependence (WAW hazard): write after write.

Denoted by $\mathrm{S}_{1} \mathrm{~d}^{0} \mathrm{~S}_{2}$

## Dependence Concepts

## Source and Sink

Source: the statement (instance) executed earlier Sink: the statement (instance) executed later
Graphically, a dependence is an edge from source to sink
$\mathrm{S}_{1} \quad \mathrm{PI}=3.14$
$\mathrm{S}_{2} \quad \mathrm{R}=5.0$
$\mathrm{S}_{3} \quad \mathrm{AREA}=\mathrm{PI} * \mathrm{R} * * 2$

## Dependence in Loops

Let us look at two different loops:

- In both cases, statement $S_{\text {I }}$ depends on itself
- However, there is a significant difference
- We need a formalism to describe and distinguish such dependences

## Data Dependence Analysis

Objective: compute the set of statement instances which are dependent

Possible approaches:
$\square$ Distance vector: compute an indicator of the distance between two dependent iteration
$\square$ Dependence polyhedron: compute list of sets of dependent instances, with a set of dependence polyhedra for each pair of statements

## Program Abstraction Level

Statement

$$
\begin{gathered}
\text { For }(\mathrm{i}=\mathrm{I} ; \mathrm{i}<=10 ; \mathrm{i}++) \\
\mathrm{A}[\mathrm{i}]=\mathrm{A}[\mathrm{i}-\mathrm{I}]+\mathrm{I}
\end{gathered}
$$

Instance of statement

$$
A[4]=A[3]+1
$$

## Iteration Domain

Iteration Vector
A n-level loop nest can be represented as a n-entry vector, each component corresponding to each level loop iterator

| For $\left(\mathrm{x}_{1}=\mathrm{L}_{1} ; \mathrm{x}_{1}<\mathrm{U}_{1} ; \mathrm{x}_{1}++\right)$ |
| :--- |
| $\ldots$ |
| For $\left(\mathrm{x}_{2}=\mathrm{L}_{2} ; \mathrm{x}_{2}<\mathrm{U}_{2} ; \mathrm{x}_{2}++\right)$ |
| $\ldots$ |
|  |
| $\quad$ For $\left(\mathrm{x}_{\mathrm{n}}=\mathrm{L}_{\mathrm{n}} ; \mathrm{x}_{\mathrm{n}}<\mathrm{U}_{\mathrm{n}} ; \mathrm{x}_{\mathrm{n}}++\right)$ |
|  |
| $\quad$ some statement $\mathrm{S}_{1}>$ |

$$
\vec{x}=\left(\begin{array}{c}
x 1 \\
x 2 \\
\cdot \\
\cdot \\
\cdot \\
x n
\end{array}\right)
$$

The iteration vector $(2, I, \ldots)$ denotes the instance of $S_{1}$ executed during the 2 nd iteration of the $X_{1}$ loop and the Ist iteration of the $X_{2}$ loop

## Iteration Domain

Dimension of Iteration Domain: Decided by loop nesting levels Bounds of Iteration Domain: Decided by loop bounds

Using inequalities

$$
\begin{aligned}
& \text { For }(\mathrm{i}=1 ; \mathrm{i}<=\mathrm{n} ; \mathrm{i}++) \\
& \text { For }(\mathrm{j}=1 ; \mathrm{j}<=\mathrm{n} ; \mathrm{j}++) \\
& \text { if }(\mathrm{i}<=\mathrm{n}+2-\mathrm{j}) \\
& \mathrm{b}[\mathrm{j}]=\mathrm{b}[\mathrm{j}]+\mathrm{a}[\mathrm{i}] ;
\end{aligned}
$$

$$
\begin{gathered}
1 \leq i \leq n, 1 \leq j \leq n \\
i \leq n+2-j
\end{gathered}
$$

## Modeling Iteration Domains

Representing iteration bounds by affine function:

$$
\begin{gathered}
1 \leq i \leq n:\left[\begin{array}{cc}
1 & 0 \\
-1 & 0
\end{array}\right]\binom{i}{j}+\binom{-1}{n} \geq 0 \\
1 \leq j \leq n:\left[\begin{array}{cc}
0 & 1 \\
0 & -1
\end{array}\right]\binom{i}{j}+\binom{-1}{n} \geq 0 \\
\mathrm{i} \leq n+2-j:\left[\begin{array}{ll}
-1 & -1
\end{array}\right]\binom{i}{j}+(n+2) \geq 0 \\
{\left[\begin{array}{cc}
1 & 0 \\
-1 & 0 \\
0 & 1 \\
0 & -1 \\
-1 & -1
\end{array}\right]\binom{i}{j}+\left(\begin{array}{c}
-1 \\
n \\
-1 \\
n \\
n+2
\end{array}\right) \geq \overrightarrow{0}}
\end{gathered}
$$

## Loop Normalization

Algorithm:
Replace loop boundaries and steps:

$$
\text { for }(\mathrm{i}=\mathrm{L}, \mathrm{i}<\mathrm{U}, \mathrm{i}=\mathrm{i}+\mathrm{S}) \rightarrow \text { for }(\mathrm{i}=\mathrm{I}, \mathrm{i}<(\mathrm{U}-\mathrm{L}+\mathrm{S}) / \mathrm{S}, \mathrm{i}=\mathrm{i}+\mathrm{I})
$$

Replace each reference to original loop variable $i$ with:
i*S S S + L

## Examples: Loop Normalization

```
For (i=4; i<=N; i+=6)
    For (j=0; j<=N; j+=2)
        A[i] = 0
```

For (ii=1; ii<=(N+2)/6; ii++)
For $(\mathrm{jj}=1 ; \mathrm{j} \mathrm{j}<=(\mathrm{N}+2) / 2 ; \mathrm{j}++$ )
$\mathrm{i}=\mathrm{ii} * 6-6+4$
$j=j j * 2-2$
$\mathrm{A}[\mathrm{i}]=0$

## Distance/Direction Vectors

The distance vector is a vector $\mathrm{d}($ sink, source) such that: $\mathrm{d}_{\mathrm{k}}=\operatorname{sink}_{\mathrm{k}}-$ source $_{\mathrm{k}}$.
i.e., the difference between their iteration vectors sink - source!!
The direction vector is a vector $\mathrm{D}(\mathrm{i}, \mathrm{j})$ such that:
$D_{k}="<"$ if $d(i, j) k>0 ;$
$\mathrm{D}_{\mathrm{k}}=">$ " if $\mathrm{d}(\mathrm{i}, \mathrm{j}) \mathrm{k}<0$;
$\mathrm{D}_{\mathrm{k}}=$ "=" otherwise.

## Example 1:

$$
\begin{array}{ll} 
& \mathrm{DO} \mathrm{I}=1, \mathrm{~N} \\
\mathrm{~S}_{1} & \mathrm{~A}(\mathrm{I}+1)=\mathrm{A}(\mathrm{I})+\mathrm{B}(\mathrm{I}) \\
& \text { ENDDO }
\end{array}
$$

$\square$ Dependence distance vector of the true dependence: source (write): A(I+1); sink (read): A(I)
$\square$ Consider a memory location $\mathrm{A}(4)$ iteration vector of source: (3) iteration vector of sink: (4)
$\square$ Distance vector: $(4)-(3)=(1)$
$\square$ Direction vector: (<)

## Example 1:

$$
\begin{aligned}
& \\
& \\
& \\
& \mathrm{S}_{1} \mathrm{DO} \mathrm{I}=1, \mathrm{~N} \\
& \mathrm{~A}(\mathrm{I}+1)=\mathrm{A}(\mathrm{I})+\mathrm{B}(\mathrm{I}) \\
& \\
& \text { ENDDO }
\end{aligned}
$$

$\square$ Dependence distance vector of the true dependence: source (write): A(I+1); sink (read): A(I)
$\square$ More general reasoning:
$\square$ Consider a memory location $\mathrm{A}(\mathrm{x})$ iteration vector of source: $(x-1)$ iteration vector of sink: (x)
$\square$ Distance vector: $(x)-(x-1)=(1)$
$\square$ Direction vector: ( $<$ )

Example 2:

$$
\begin{aligned}
& \text { DO } \mathrm{I}=1, \mathrm{~N} \\
& \mathrm{DO} \mathrm{~J}=1, \mathrm{M} \\
& \mathrm{DO} \mathrm{~K}=1, \mathrm{~L} \\
& \mathrm{~S} 1 \quad \mathrm{~A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{~J}, \mathrm{~K})+10 \\
& \text { ENDDO } \\
& \text { ENDDO } \\
& \text { ENDDO }
\end{aligned}
$$

What is the dependence distance vector of the true dependence?
What is the dependence distance vector of the antidependence?

## Example 2:

$$
\begin{aligned}
& \mathrm{DO} \mathrm{I}=1, \mathrm{~N} \\
& \mathrm{DO} \mathrm{~J}=1, \mathrm{M} \\
& \quad \mathrm{DO} \mathrm{~K}=1, \mathrm{~L} \\
& \mathrm{~S} 1 \quad \mathrm{~A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{~J}, \mathrm{~K})+10 \\
& \text { ENDDO } \\
& \text { ENDDO } \\
& \text { ENDDO }
\end{aligned}
$$

For the true dependence:
Distance Vector: ( $1,0,-1$ )
Direction Vector: $(<,=,>)$
For the anti-dependence:
Distance Vector: $(-1,0,1)$
Direction Vector: $(>,=,<)$
sink happens before source: the assumed anti-dependence is invalid!

## Example 3:

$$
\begin{aligned}
& \text { DO } \mathbf{K}=\mathbf{1}, \mathbf{L} \\
& \text { DO } \mathrm{J}=1, \mathrm{M} \\
& \mathbf{D O} \mathbf{I}=\mathbf{1}, \mathbf{N} \\
& \mathrm{S} 1 \quad \mathrm{~A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{~J}, \mathrm{~K})+10 \\
& \text { ENDDO } \\
& \text { ENDDO } \\
& \text { ENDDO }
\end{aligned}
$$

What is the dependence distance vector of the true dependence?
What is the dependence distance vector of the antidependence?

## Example 3:

$$
\begin{aligned}
& \text { DO } \mathbf{K}=\mathbf{1}, \mathbf{L} \\
& \text { DO } \mathrm{J}=1, \mathrm{M} \\
& \mathbf{D O} \mathbf{I}=\mathbf{1}, \mathbf{N} \\
& \mathrm{S} 1 \quad \mathrm{~A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{~J}, \mathrm{~K})+10 \\
& \text { ENDDO } \\
& \text { ENDDO } \\
& \text { ENDDO }
\end{aligned}
$$

For the true dependence:

$$
\begin{aligned}
& \text { Distance Vector: }(-1,0,1) \\
& \text { Direction Vector: }(>,=,<)
\end{aligned}
$$

For the anti-dependence:
Distance Vector: ( $1,0,-1$ )
Direction Vector: $(<,=,>)$
The assumed true dependence is invalid!

Example 2
DO $\mathrm{I}=1, \mathrm{~N}$
$\mathrm{DO} \mathrm{J}=1, \mathrm{M}$
$\mathrm{DO}=1, \mathrm{~L}$
$\mathrm{~S} 1 \quad \mathrm{~A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{J}, \mathrm{K})+10$
ENDDO
ENDDO
ENDDO

Example 3

$$
\begin{aligned}
& \text { DO } \mathbf{K}=\mathbf{1}, \mathbf{L} \\
& \operatorname{DO~} \mathrm{J}=1, \mathrm{M} \\
& \mathrm{DO} \mathbf{I}=\mathbf{1}, \mathbf{N} \\
& \mathrm{S} \quad \mathrm{~A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{~J}, \mathrm{~K})+10 \\
& \text { ENDDO } \\
& \text { ENDDO } \\
& \text { ENDDO }
\end{aligned}
$$

$\square$ True dependence turns into an anti-dependence. "Write then read" turns into "read then write".
$\square$ Reflected in direction vector of the true dependence:
$(<,=,>)$ turns into $(>,=,<)$

## Example 4:

$$
\begin{aligned}
& \text { DO } \mathbf{J}=\mathbf{1}, \mathbf{M} \\
& \text { DO } \mathbf{I}=\mathbf{1}, \mathbf{N} \\
& \quad \mathrm{DO} \mathrm{~K}=1, \mathrm{~L} \\
& \mathrm{~S} 1 \quad \mathrm{~A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{~J}, \mathrm{~K})+10 \\
& \quad \text { ENDDO } \\
& \text { ENDDO } \\
& \text { ENDDO }
\end{aligned}
$$

What is the dependence distance vector of the true dependence?
What is the dependence distance vector of the anti-dependence? Is this program equivalent with Example 2?

Example 2

| DO I $=1, \mathrm{~N}$ |  |
| :---: | :---: |
| DO $\mathrm{J}=1, \mathrm{M}$ |  |
| DO K = 1, L |  |
| S1 A(I+ |  |
| ENDDO |  |
| ENDDO |  |
| ENDDO |  |
| Example 4 |  |
| DO J = 1, M |  |
| DO I = 1, N |  |
| DO K = 1, L |  |
| S1 $\mathrm{A}(\mathrm{I}+1, \mathrm{~J}, \mathrm{~K}-1)=\mathrm{A}(\mathrm{I}, \mathrm{J}, \mathrm{K})+$ |  |
| ENDDO |  |
| ENDDO |  |
| ENDDO |  |

Consider the true dependence

| distance vectors | direction vectors |
| :---: | :---: |
| (1,0, -1) | $\begin{aligned} & \text { source }(\langle,=,\rangle) \text { sink } \\ & \text { write } \end{aligned}$ |
| (0, 1, -1) | $\begin{gathered} \text { sourcee }(=,\langle,\rangle) \text { sink } \\ \text { write } \\ \text { read } \end{gathered}$ |

So, it is still a true dependence.

True dependence stays as true dependence. "Write then read" stays as "Write then read".
$\square$ Reflected in direction vector of the true dependence: ( $<,=,>$ ) turns into ( $=,<,>$ )

## Reordering Transformations

Definition:
merely changes the order of execution of the code no adding or deleting

A reordering transformation does not eliminate dependences However, it can change the execution order of original sink and source, causing incorrect behavior
"Any reordering transformation that preserves every dependence in a program preserves the meaning of that program."
---- Fundamental Theorem of Dependence

## Theorem of loop reordering

Direction Vector Transformation
Let T be a reordering transformation that is applied to a loop nest and that does not rearrange the statements in the body of the loop.
Then the transformation is valid if, after it is applied, none of the direction vectors for dependences with source and sink in the original nest has a leftmost non- " $=$ " component that is " $>$ ".

Follows from Fundamental Theorem of Dependence:
All dependences exist
None of the dependences have been reversed

## Procedure to Check Validity of a Loop Reordering

I. List the direction vectors of all types of data dependences in the original program
2. According to the new order of loops, exchange the elements in the direction vectors to derive the new direction vectors.
3. If all the direction vectors have a "<" as the first non-"=" sign, the transformation is valid.
A all-"=" vector will stay as all-"=" vector; it won't affect the correctness of loop reordering.

## Example
